#### Abstract

Researchers concerned with the development of cognitive functions are in need of standardized material that can be used with both adults and children. The present article provides normative measures for 400 line drawings viewed by 5- and 6 -yearold children. The three variables obtained-name agreement, familiarity, and visual complexity-are important because of their potential effect on memory and other cognitive processes. The normative data collected in the present study indicate that young children are different from adults in both the name most frequently assigned and the number of alternative names provided. The alternative names given by the children are either coordinate names or names of objects that are visually similar to the pictured object. In addition, the failure (to name) rate is higher among young children compared to adults. Thus, we conclude that unequivocal interpretation of age-related differences in cognitive functions can be made only when age-appropriate pictorial stimuli are chosen. © 1997 Academic Press

Pictures are often used by cognitive psychologists investigating the development of cognitive functions. Different attributes of the picture, such as object or picture familiarity (Lachman \& Lachman, 1980), word frequency

The authors thank Mr. Charles L. Brown III for computer programming, Ms. Elisabeth Schrieber for helping with data analysis, and Drs. Carla Johnson and Sandra Waxman for their helpful comments on an earlier version of the manuscript. The authors also thank the children who participated in the study and the principal and teachers of Manhattan Day School for their cooperation. This research was supported in part by Grant HD14959 from NICHD. Address reprint requests to Dr. Yael M. Cycowicz, New York State Psychiatric Institute, 722 West 168th Street, Unit 58, New York, NY 10032. Fax: (212) 781-2661. E-mail: cycowic@ nypimail.cpmc. columbia.edu.
(Oldfield \& Wingfield, 1965), and age of acquisition (Carroll \& White, 1973), are known to correlate with naming latency and to affect memory, particularly retrieval processes.

Normative data for pictures have been collected by Snodgrass and Vanderwart (1980) for young adults and by Berman, Friedman, Hamberger, and Snodgrass (1989) for 8- to 10 -year-old children, but similar systematic information is still unavailable for younger children. There is evidence that name agreement (Berman et al., 1989; Johnson \& Clark, 1988), picture familiarity (Berman et al., 1989), and age of acquisition (Walley \& Metsala, 1992) differ between young children and adults. Researchers working with this population are aware of the need to use age-appropriate materials, and therefore choose pictorial stimuli from coloring books and other materials designed for young children. A drawback of this approach is that considerable variation exists between different renderings of the same concepts, such as in amount of detail, object positions, and size. Thus, it is difficult to compare data sets acquired in different laboratories. Moreover, developmental studies require comparison between groups that vary in age and that will most likely differ in their cognitive performance. For example, Graf (1990) obtained a smaller priming effect in an implicit memory task with children compared to adults when the stimulus materials were normed for adults. However, when the stimulus materials were normed for children, no difference in the priming effect was found between children and adults. Thus, without the use of ageappropriate stimuli it is difficult to determine whether age-related differences are due to immature memory systems or to the absence of particular items in the lexical and/or semantic networks of the children.

The motivation for the present study was to obtain a normative database for pictorial material that will be useful for future studies with both young children and adults. We recruited 5- and 6 -year-old children, tested them individually, and asked them in several sessions to name 400 pictures presented one at a time. These 400 pictures included the 260 line drawings that were normed for young adults by Snodgrass and Vanderwart (1980) and for 8 - to 10 -year-old children by Berman et al. (1989) (Set 1), the 61 pictures normed by Berman et al. (1989) for both young adults and 8 - to 10 -year-old children (Set 2), and 79 new pictures (Set 3). In addition to naming, the children were asked to rate the complexity of the pictures and their familiarity with the concept depicted by each picture.

Picture naming in children appears to be affected by variables similar to those that affect picture naming by adults. Therefore, we will first briefly review the literature that deals with the effect of different pictorial characteristics on adult performance, and then we will provide some background on pictorial processing in children.

Studies of picture naming in adults are based upon measurement of the time it takes for a subject to produce the first name that comes to mind (Carroll \& White, 1973; Humphreys, Riddoch, \& Quinlan, 1988; Oldfield \& Wingfield,

1965; Paivio, Clark, Digdon, \& Bons, 1989; Snodgrass \& McCullough, 1986; Snodgrass \& Yuditsky, 1996). The underlying rationale is that the picture's attributes affect the length of time it takes to access the picture's name. Correlations between naming latency and word frequency, concept familiarity, age of acquisition, visual complexity, and word length have been used to assess which of these variables is the determining factor in the processes that underlie picture naming. Those attributes that prolong naming latency in adults have also been shown to affect the level of naming accuracy and/or latency in young children (Johnson \& Clark, 1988; Johnson, 1992).

Lachman and Lachman (1980) suggest that the crucial variable affecting naming latency is the codability or the uncertainty of the name. Uncertainty is theoretically defined as the number of names that are connected to an object's representation. In practice, it is possible to measure uncertainty by determining the number of names given by a group of native English speakers. The number of alternative names elicited by a picture is reflected in the $H$ statistic that has been used as a measure of name agreement in previous picture-naming studies (Berman et al., 1989; Snodgrass \& Vanderwart, 1980) and is also computed in the current study.

Oldfield and Wingfield (1965) argued that the time it takes to name an object is a linear function of the log frequency of the occurrence of the object name in written language. Humphreys et al. (1988) claimed that word frequency affects naming latency only for pictures chosen from categories in which items are visually different from each other. Carroll and White (1973), however, argued that pictures whose names were learned early in life are named more rapidly than pictures with names that were learned at a later age and, therefore, age of acquisition and not word frequency determines naming latency. In a recent study, Morrisson, Ellis, and Quinlan (1992) reported additional evidence in support of the importance of age of acquisition over word frequency and added that latency is affected more by the length of the picture's name than by word frequency. Snodgrass and Yuditsky (1996) asked college students to estimate the age at which they learned 250 of the 260 Snodgrass and Vanderwart (1980) concepts. Although most of the concepts were learned at an early age, subjects placed age of acquisition for some concepts as late as 13 years. This suggests that some of the concepts used in the present study may not have been acquired by the 5 - to 7 -year-old children. This would be reflected in low name agreement and/or in errors in which pictures are named with the names of objects that look similar to tested concepts.

Healthy adults are highly accurate in picture-naming tasks, but patients who have suffered from various types of neurological damage produce many incorrect names. Analysis of the errors made by these patients in picturenaming tasks can provide more information about the naming process. Most of the current models assume at least three serially organized stages involved in picture naming: object identification, name activation, and response generation (Lachman \& Lachman, 1980; Paivio et al., 1989; Snodgrass \& McCul-
lough, 1986). In some models an additional semantic activation stage is assumed to occur before name activation (Humphreys et al., 1988; Morrison et al., 1992). For example, Humphreys et al. (1988) obtained naming error data from a patient who had a deficit in identifying visually presented objects, but was able to name with normal accuracy the same objects when he touched them or when their definitions were presented auditorily. The patient was more likely to correctly name high frequency concepts from structurally distinct categories, suggesting that access to semantic or name information depends upon the degree of similarity between the depicted object and other concepts within the same category.

The processes subserving picture naming are assumed to involve the activation of multiple candidates that share either perceptual or functional characteristics. Under speeded naming conditions more errors are made, because there is not enough time to distinguish between the different candidates. Vitkovitch, Humphreys, and Lloyd-Jones (1993) claimed that the types of errors produced under deadline conditions depended upon the category to which the picture belonged. They defined two kinds of categories, one in which the members are perceptually similar, like fruits or quadruped animals, and one in which members are perceptually distinct from one another, such as toys or furniture. Categories of the first type are defined as "structurally similar" whereas those of the second type are termed "structurally dissimilar." Vitkovitch et al. (1993) hypothesized that, for items drawn from structurally similar categories, errors would be names of concepts that are perceptually and functionally similar to the picture. Such naming errors were denoted "visual + semantic" as opposed to "pure semantic" and "pure visual" errors. Naming errors from structurally dissimilar categories were expected to come from all three error types and thus to be more diverse than those of structurally similar categories. Their findings confirmed this hypothesis, although in both structurally similar and structurally dissimilar categories "visual + semantic' errors predominated.

Young children are less efficient in picture-naming tasks than are older children and adults (Wiegel-Crump \& Dennis, 1986). Even under no time constraint they fail to name pictures as accurately as adults. With maturation, children respond faster and reach adult levels of accuracy. Even under the assumption that picture naming in young children involves the same threeor four-stage model as in adults, it remains unknown whether maturation affects these stages similarly or whether specific stages are affected differentially. Johnson (1992) found that name uncertainty (pictures with multiple possible names) affects children's accuracy and latency, and she showed its effect on postidentification stages (name activation, response generation, or both). Thus, an uncertainty measure (such as the $H$ statistic used here) is essential when researchers select pictorial stimuli for studies with children. In addition, it is not clear whether or how young children's errors depend upon categorical distinctions because young children's categorical knowledge is still developing. For example, Nelson (1974) claimed that subclass catego-
ries (insects vs animals, or fruits and vegetables vs food) are less clearly defined by children. Sperber, Davies, Merill, and McCauley (1982) argued that visually similar categories develop earlier than conceptual categories. Therefore, young children might not exhibit the effect found by Vitkovitch et al. (1993) of more "visual + semantic" errors for structurally similar categories, because this distinction may not yet be within the young child's cognitive repertoire.

There are many questions one might ask about the processes involved in picture naming by young children. However, the main goal of this paper is to provide normative data for pictorial stimuli for use with young children. The normative data include the most common name given to each of the 400 concepts (modal name), name agreement, picture familiarity, visual complexity, word frequency, and word length. Because the name agreement of many concepts is low for young children, we present the alternative names and describe the pattern of naming errors produced by our sample of young children.

## METHOD

## Subjects

Children. Thirty children in kindergarten (21), first grade (7), and second grade (2) participated in the study. Their mean age was 6.07 years (range: $5.1-7.6 ; S D=0.73$ ) and 14 were girls. One additional child did not complete the task and was excluded from the analyses. Most of the children (26) were recruited through Manhattan Day School in New York City, and all were native English speakers. All read at or above grade level as assessed by the Wide Range Achievement Test (WRAT, mean standard score $=103.5$; SD $=15.88$ ). A socio-economic status (SES) index (Watt, 1976), with a range of 20 (graduate professional) to 134 (unskilled person), was obtained for each child (mean $=30.36 ; S D=10.00$ ) based upon the education level and occupation of the children's parents. Informed assent and consent forms were obtained from the children and their parents. After task completion subjects received a small gift.

Adults. Thirty volunteers took part in the study, half of whom were paid for their participation. One additional subject did not follow the instructions and was excluded from the analyses. Their mean age was 26.23 years (range: $19-35 ; S D=3.97$ ) and 11 were females. All subjects were native English speakers. The SES level for the adults was $48.24(S D=18.66)$. Because the adult participants were mostly students, their SES scores were higher, indicating lower SES, than those of the young children.

## Stimulus Materials

Children. The pictures were unambiguous line drawings of common objects. There was a total of 400 pictures (presented in Appendix A). Set 1 included 260 pictures (numbered 1-260 in Appendix A) from the adult norms
of Snodgrass and Vanderwart (1980), Set 2 was composed of 61 pictures (numbered 261-321 in Appendix A) from the child and adult norms of Berman et al. (1989), and Set 3 included 79 pictures taken from a number of different sources (numbered 322-400 in Appendix A). These were stylistically similar to those in the Snodgrass and Vanderwart (1980) and Berman et al. (1989) normative data sets. The intended names of the 400 pictures (along with the norms measures) are presented in Appendix B. The pictures as well as their corresponding normative data can be downloaded from the following Internet address: http://www.nyspi.cpmc.columbia.edu/nyspi/ respaprs/picnorm.htm. The 400 pictures were randomized separately for each subject and then divided into 5 lists, each containing 80 items.

Adults. The picture set for the adults included the 79 pictures from Set 3 plus the picture of the zebra taken from the Snodgrass and Vanderwart database. The zebra was added to create an even number of pictures and was not included in the analyses. The pictures were randomized separately for each subject and then divided into 5 lists each containing 16 items.

## Procedures

Children. Each child was tested individually, in five sessions, at the school he/she attended. The child was tested on 5 different days for a period of time that varied between subjects and usually ranged from 20 to 40 min . In the first session, the child's reading level was estimated using the reading subtest of the WRAT. Next, the picture-naming task was administered for the first list of pictures. In the following four sessions only picture naming was performed with the remaining four lists of pictures.

In the naming task, the child viewed one picture at a time on a Macintosh (classic II) computer screen. The picture remained on the screen until the child provided the experimenter with information about the name, familiarity, and visual complexity of the picture. On average, a picture was viewed for about 15 s . The instructions the children received were identical to those described in Berman et al. (1989) and their ratings were scored on a threepoint scale ( 1,3 , and 5 ; see below) rather than a five-point scale as had been used in the Snodgrass and Vanderwart (1980) study with adults. This was done because Berman et al. had determined (in pilot testing) that even older children (ages $8-10$ ) did not assign ratings across the full range of numerical values in the five-point rating scale supplied by the experimenter. For name agreement the child was asked 'What is this picture?', To obtain a score for familiarity the child was asked "How often do you think about this thing? A lot (scored 5), sometimes (scored 3), or very little (scored 1)?'’ After giving the answer, the subject was asked "How difficult is it to draw or to trace this picture, is it hard (scored 5), medium (scored 3), or easy (scored 1)?" The answer to this question was used as a rating of the visual complexity of the picture. For cases in which the child did not recognize the object depicted, the next picture was presented. When a child could not name the picture, questions were asked that would aid in determining whether the child did or
did not know the concept. This is important because young children comprehend many concepts that they fail to express verbally. The experimenter asked questions like "What can you do with it," or "Where do you see it?" If the answer indicated that the child did have knowledge about the object, then he/ she was asked to answer the familiarity and the visual complexity questions. A short practice block was presented using pictures (not in the set of 400 experimental pictures) that were pasted onto index cards. To anchor the familiarity and complexity scales, a comparison between familiar and unfamiliar objects was demonstrated (ice cream and canteen), as was a comparison between pictures that were visually simple and those that were visually complex (triangle and tape recorder). All subjects' answers were entered by the experimenter into the computer database online.

Adults. Each subject was tested individually (half in our laboratory and half outside the laboratory in a quiet room in a community center in Manhattan) in one five-block session. Subjects were taught how to perform the task, i.e., how to enter their responses and how to use the computer. They were told to type the first name that comes to mind upon seeing the picture without concern for spelling. If they did not recognize the object or did not remember the name of the object they were told to select the appropriate option that appeared on the screen: "do not know object'" or "do not know name." In addition, subjects were asked to rate the familiarity and visual complexity of the pictures they recognized. Both familiarity and visual complexity were explained to the subjects in the same way as in Snodgrass and Vanderwart (1980). Subjects were told to rate familiarity by estimating how often they thought about the concept in their daily lives. The emphasis was on the concept itself rather than the way it was drawn. Subjects were given a fivepoint rating scale for familiarity, with 1 representing the least familiar and 5 the most familiar. Similarly, there was a five-point scale for visual complexity, with 1 representing the least complex and 5 the most complex. Complexity was defined as the amount of detail and number of lines in the drawing. Subjects advanced from picture to picture at their own pace, and the average session time was about 20 min .

## Analyses

The following information was obtained for every picture.
Modal name. A modal name is defined as the name given by the majority of subjects. Errors were classified according to adult criteria, i.e., names that did not accurately describe the concept. An example of such an occurrence is the picture of the nail file; none of the children recognized the object as a tool with which to file nails, and their model name is "knife." Two judges classified the modal names that were different for children and adults. The children's modal names were classified into one of the following categories: synonym, superordinate, subordinate, component (part of), coordinate, and failure. Coordinates were defined as object names that were in the same category, whereas 'failures' were defined as names that either were visually
similar to or had no relationship to the tested concepts. "Failure" responses included names that were non-nouns (e.g., 'to fix stuff'') or non-object (e.g., 'music'"). Note also that classifying a name as a coordinate is dependent upon the definition of the category, which can be more or less inclusive. For example, 'apple" and 'cucumber'' can be exemplars of two different categories - they can be categorized as fruits and vegetables, respectively, or as members of the same category, food. However, when both are classified as food they would be considered coordinates of each other, otherwise they would be classified as failures. Because the categories chosen are somewhat arbitrary, the coordinate responses can be viewed, to some extent, as failures. A third judge (Y.C.) examined the judges' classifications and resolved discrepancies. There were 10 occurrences (of a total of 89 ) in which the two judges did not agree with each other.

The same two judges reviewed individual subjects' non-modal names and classified each response into one of the above categories with respect to the adults' modal name. The judges did not agree with each other about $5 \%$ of the time, and a third judge (Y.C.) resolved these discrepancies.

Name agreement. There are two measures of name agreement. The first is the percentage of subjects naming the picture with its modal name. The second is the information statistic, $H$, which was computed for each picture by the formula (taken from Snodgrass \& Vanderwart, 1980)

$$
H=\sum_{i=1}^{\hat{}} P_{i} \log _{2}\left(1 / P_{i}\right),
$$

where $k$ refers to the number of different names given to each picture, and $P_{i}$ is the proportion of subjects who gave each name. The computation of $H$ does not take into account "do not know name" (DKN) or "do not know object'" (DKO) responses (for more information see Snodgrass \& Vanderwart, 1980). For the percentage measure, a higher number signifies greater name agreement. However, for the $H$ measure, a lower number signifies greater name agreement; for example, when all subjects supply the same name, the value is 0 . A higher value indicates that a greater number of alternative names was supplied. The criteria used for counting different instances of names were the same as those used in the Snodgrass and Vanderwart (1980) study.

Familiarity. The familiarity ratings for the young children were assigned numerical scores of 1,3 , and 5 such that 1 corresponds to an unfamiliar concept (response of "a little"), 3 corresponds to a somewhat familiar concept (response of 'sometimes'"), and 5 corresponds to a highly familiar concept (response of 'a lot'"). Adults used a five-point rating scale with all of the values between 1 and 5 . When a subject did not know the object depicted (DKO), a rating of familiarity was not available. Such occurrences were not included in computing the means (i.e., only the actual number of subjects who supplied ratings was used in computing mean values).

Visual complexity. The visual complexity ratings for the young children were assigned numerical scores of 1,3 , and 5 such that 1 corresponds to a
simple drawing (response of "easy'"), 3 corresponds to a less simple drawing (response of 'medium''), and 5 corresponds to a visually more complex drawing (response of "hard'"). Adults used a five-point rating scale with all of the values between 1 and 5 . When subjects did not know the object depicted (DKO), a rating of visual complexity was unavailable. As for familiarity, such occurrences were not included in computing the means.

Word frequency. We used the third-grade frequency in print counts, which is the youngest age group in the American Heritage word frequency count (Carroll, Davis, \& Richman, 1971). The frequency count is expressed as occurrences per million.

Length. The number of letters in the modal name constituted length.
Age of acquisition. The ages of acquisition of 250 of the 260 Snodgrass and Vanderwart (1980) concepts were taken from Snodgrass and Yuditsky (1996).

Naming latency. Naming latency was measured as the time from picture onset until a key of the first letter of the name was pressed on the computer keyboard. The adult subjects pressed the letter on the keyboard themselves. Children told the experimenter the name of the picture presented, and the experimenter immediately pressed a key corresponding to the first letter of the name given. This is not the common way of measuring naming latency. However, because there is a high correlation between vocal naming latency and keystroke latency (Paivio et al., 1989), this indirect measure was used here.

The three sets of drawings, 260 items from Snodgrass and Vanderwart (1980), 61 items from Berman et al. (1989), and the additional 79 items, were analyzed separately, and two-tailed $t$ tests for paired samples were used (using the picture as the unit of measurement) to compare the data of the young children with the data of adults and older children. Missing values were excluded pairwise. In addition, two-tailed $t$ tests were used for comparisons among the three picture sets. Because many comparisons were performed, a significant difference was defined conservatively at an $\alpha$ level of 0.01 .

## RESULTS AND DISCUSSION

## Snodgrass and Vanderwart Pictures (Set 1)

Table 1 in Appendix B presents the data for the 260 pictorial stimuli, listed in alphabetical order according to their presentation in Appendix A (Items $1-260$ ). The 6 -year-old children provided modal names that differed from the adults' modal names for 35 of the stimuli ( $13.5 \%$; denoted in Appendix B in boldface). These results contrast with those for 8 - to 10 -year-olds reported by Berman et al. (1989), in which modal names differed between older children and adults in only 14 cases (5\%). The 35 concepts with different modal names were divided into classes according to the relationship between young children's and adults' modal names. Five concepts were classified as syn-
onyms, for example, teapot and kettle. Nine concepts were given a superordinate modal name; for example, bug for beetle or bird for eagle. Component names relate as part to whole, such as salt and salt shaker. Four modal names given were component names of the concept. Coordinate names occurred 14 times and included naming substitutions such as apple for cherry and trumpet for french horn. Three concepts were classified as failures. These are "ashtray," "nail file," and "thimble." In the case of the nail file, most children thought that the picture was of a knife, a visually similar object. The picture of the thimble was recognized by six subjects, but the majority of the children called it "a cup,' due to its visual similarity. However, the picture of the ashtray was not recognized at all by 24 (of 30) subjects (DKO responses). The other 6 subjects gave different names, all of which were considered failures. This is a very interesting finding, because in the Snodgrass and Vanderwart study (1980), all the adults named the ashtray correctly and in the Berman et al. study (1989), $35 \%$ of the children named the object correctly. This not only seems to be a function of age, but may also reflect a change in culture. Due to laws that forbid smoking in public areas, young children have less exposure to cigarette ashtrays, which may explain its apparent absence from their semantic knowledge base.

Although Snodgrass and Vanderwart (1980) reported only a $1.7 \%$ failure rate in providing names, the present study elicited DKN and DKO responses at a rate of $9.8 \%$. Many of the concepts for which the children's modal name matched that of the adults were also assigned a large number of alternative names. We deal with the issue of alternative names in greater detail in the section on naming errors.

Table 1 presents the summary statistics for the six measures obtained for the young children. It also includes the summary statistics for age of acquisition reported by Snodgrass and Yuditsky (1996) and the summary statistics for naming latency. The corresponding measures for adults taken from Snodgrass and Vanderwart (1980), and for older children taken from Berman et al. (1989), are presented as well. It is apparent that whereas the summary measures of adults and older children are very similar to each other, the summary measures for young children differ widely.

The measure of name agreement expressed by the information statistic $H$ is highest for the young children, demonstrating that the youngest subjects produce more alternative names than the subjects in the other two groups. The highest value for the information statistic $H$ in the young children is 3.25 compared to 2.55 and 2.58 for adults and older children, respectively. Interestingly, the 25 th percentile (Q1) is relatively small for the young children. This is a result of the fact that the young group has more instances of DKO and DKN responses that did not enter into the computation of the $H$ statistic. For example, the concept ' wagon'" has an $H$ value of 0 in the young children, which means that all the subjects provided the same name. However, only 23 of the 30 subjects named the picture, whereas the other 7 subjects responded either DKO or DKN. Information about the number

of subjects who provided the modal name is expressed by the percentage measure of name agreement. Two-tailed $t$ tests between young children and each of the other groups were found to be significantly different ( $p<.001$ ) for both the $H$ and percentage measures of name agreement.

Two-tailed $t$ tests of the familiarity measure revealed that familiarity was lower in young children than in the adults or the older children ( $p<.001$ ). Young children show a smaller range and less variation in their ratings of familiarity. These results are expected because young children have less experience with some of the concepts. Unlike the familiarity measure, the comparison of the visual complexity ratings revealed that the young children's rating is similar to that of the adults. However, comparison of young children with older children did result in a significant difference between the groups ( $p<.001$ ).

The number of letters in a word is a relevant variable in performance that involves short-term memory. In particular, there is a linear relationship between the number of words recalled and the rate at which they can be articulated (Baddeley, Thomson, \& Buchanan, 1975). This relationship was observed with children as young as 4 years old (Hulme, Thomson, Muir, \& Lawrence, 1984). This suggests that young children produce shorter names when they do not use the adult modal name. This was supported by a comparison of the mean length of the modal names of the three groups. A two-tailed $t$ test revealed no significant difference between adults and older children, but a significant difference was obtained when comparing adults to young children ( $p<.001$ ). One simple reason for this is the fact that modal names provided by older children were different from those provided by adults on only 14 items, a difference which is not statistically significant. However, young children's modal names differed from the adult modal names for 35 items, and those items tended to have fewer letters. In general, it is more likely for children to choose short, simple words, because they are the ones learned earliest and consequently are better represented in their lexicons.

Each of the variables measured plays an important role in various cognitive tasks. Often the question arises as to which of the variables directly affects performance on a given task. Before this question can be answered, however, it is necessary to know the relationships among the measures. Table 2 shows the correlation matrix for the young children with the significant correlation coefficients marked with an asterisk. As expected, the two measures of name agreement show a high negative correlation. Familiarity, complexity, length, and word frequency show low intercorrelations, suggesting that they reflect orthogonal constructs. This pattern, with slightly larger values, was also found by Snodgrass and Vanderwart (1980) and Berman et al. (1989). The correlation between age of acquisition and name agreement indicates that for concepts acquired at an early age the level of agreement is high. The fact that young children's name agreement correlates less with word frequency than with age of acquisition is similar to the finding that for adults, age of acquisition has a greater influence on picture naming than do other variables (Car-

* $p<.01$.
roll \& White, 1973; Morrison et al., 1992). Note that age of acquisition used in the present study was estimated by adults.

Naming latency usually indicates the relative degree of difficulty in retrieving names from semantic memory. Although our naming latency was recorded in an indirect way, it appears to be a valuable measure that shows some degree of face validity because, as seen in Table 2, naming latency correlates significantly with each of the other variables. The correlations between naming latency and the measures of name agreement are particularly high, indicating that less time is required to access names that most subjects agreed on. That is, high name agreement is associated with a smaller number of alternative or competing names, which may explain why picture naming that involves searching this "smaller"' name-space is faster. However, in addition to name agreement, familiarity of the depicted object affects the naming process and correlates in the expected direction with naming latency.

Error analyses. The children's naming errors are generally real words in the language (only three responses were not words). However, at times they are grammatically incorrect. For example, "rolling baker'" for rolling pin or "light changing" for traffic light. This type of response is similar to DKN, because it indicates that the subjects recognize the object but cannot name it. Misidentification, such as calling asparagus a "candle" or an artichoke a 'parachute," is another common error type. These kinds of responses can be viewed as DKO responses because they indicate that the subject did not recognize the object. Alternatively, it is possible that some pictures did not clearly depict the concepts they were meant to represent, and therefore they elicited names of visually similar objects. An example of this is the picture of the thimble, which was named by 10 children as a cup. Both types of errors were considered failures. All the nondominant names given by the young children are presented in Table C1 of Appendix C (Items 1-260).

In order to characterize alternative (i.e., non-modal) names, the scheme
provided by Snodgrass and Vanderwart (1980) was followed, in which these names were classified into synonyms, superordinates, subordinates, components, coordinates, and failures. Table 3 presents the results of this classification for 14 selected categories. The categories are those used by Snodgrass and Vanderwart with the addition of the category "toys," which we though was relevant. A list of the items within each category appears in Appendix D.

In Table 3 the column labeled 'intended name" (INTEND) shows the percentage of children's responses that match the adult modal names. The category 'tool" shows the lowest percentage of adult modal names and no synonym responses. However, the 'toys'" category shows a higher percentage of adult modal names and also shows the largest percentage of synonyms; concept and synonym responses together account for $90 \%$ of responses in this category. Table 3 clearly indicates that those categories that include items outside the children's daily experience, such as tools and musical instruments, have a low percentage of adult modal names and low synonym responses. In contrast, categories that include items commonly found in children's environments, such as toys and vehicles, show a higher percentage of adult modal names and synonym responses. The insect category shows the largest percentage of superordinate responses, because children frequently refer to any kind of insect as a "bug." However, overall, most of the nonmodal names are of the coordinate class, which may indicate that children have knowledge of the category to which the concepts belong or that the children misidentified the depicted object. Most of the coordinate responses consist of objects that are visually similar to the object depicted in the drawing.

To summarize the results of Set 1, it was found that young children are less accurate in naming the 260 pictures, which is reflected in lower name agreement compared to that of adults and older children. The familiarity ratings of the young children also differ from those of the adults and older children and are consistent with the young children's lack of experience with some of the objects, such as tools and musical instruments. On the other hand, the measure of visual complexity was fairly similar between the age groups, and this suggests that familiarity does not play a role in judging visual complexity. Despite these differences, the pattern of relationship among the variables is comparable across all groups. The data do not appear to reflect perceptual or functional differences among the groups, but rather reflect the lack of knowledge of particular concepts by the young children. Therefore, pictures from this set that were rated similarly by young children and adults can be used in developmental studies of memory and other cognitive processes.

## Berman et al. Pictures (Set 2)

Table B1 in Appendix B presents the data for the 61 pictures listed in alphabetical order according to their presentation in Appendix A (Items 261321). Table C 1 in Appendix C presents all the nondominant names for these

Note. $N$, number of examplars in each category; INTEND, intended name; SYN, synonyms; SUPOR, superoridinates; SUBOR, subordinates; COMP, component includes 'part of'"; COOR, coordinates; FAIL, naming failure; DKN, don't know name; DKO, don't know object.
pictures (Items 261-321). The 6 -year-old children provided modal names that differed from the adults' modal names for 27 concepts ( $44 \%$ of the concepts) compared to 11 items ( $18 \%$ of the concepts) for which the modal names given by the older children differed from the adults' modal names in the Berman et al. (1989) study. The 27 pictures with different modal names include 4 synonyms, 6 superordinates, and 4 component names (part of). In addition, there were 8 stimuli with coordinate names and 4 failures. The failures were "box" for the picture of basin, "mirror" for the paddle, "bed"" for the pinball machine, and "refrigerator" for the picture of a safe. One more picture, that of a fishing reel, was not recognized by most children (22) and the other 7 children each gave a unique and unrelated name, so "fishing reel" does not have a modal name for this age group. Twenty-seven percent of the responses to this set of pictures were either DKO or DKN, resulting in a low mean percentage of name agreement ( $47 \%$ ).

Table 4 presents summary statistics for the six measures of the young children's responses and the summary statistics for naming latency. The corresponding measures for adults and older children taken from Berman et al. (1989) are presented as well. Two-tailed $t$ tests between young children and each of the other groups were found to be significant ( $p<.001$ ) for both measures of name agreement ( $H$ and \%), indicating, as for Set 1, that the youngest subjects produced more alternative names than subjects in the two older groups. Of the alternative names given by the young children, 8.3\% bear no relationship to the concept represented by the picture and thus were considered failures.

The young children rated the items less familiar than either the adults or the older children although this difference was not significant. Comparisons of visual complexity ratings among groups yield a significant difference only between young children and adults ( $p<.001$ ). The range and skew of the values suggest that young children tend to rate the pictures as more visually complex than do adults and older children. Comparing the mean lengths of the modal names among the three groups reveals no significant difference, although the young children do tend to use shorter names.

Table 5 shows the correlation matrix for the young children with the asterisks indicating the significant intercorrelations. As expected, the two measures of name agreement show a high negative correlation. As with Set 1 , naming latency correlates with both measures of name agreement ( $H$ and $\%$ ) and indicates that it takes less time to name pictures that have a high degree of name agreement.

To summarize, our findings for Set 2 are very similar to those for Set 1 . The young children are less accurate than older children and adults in naming Set 2 pictures. The high rate of naming failure suggests that this set includes a large number of pictures that are less familiar to the young children.
New Pictures (Set 3)
There are only four pictures in Set 3 for which the concept names we identified are slightly different from the modal names given by the adults

(see Table B2 in Appendix B). These concepts are "koala," "peas," "ray," and 'rosebud'" in which subjects named 'koala bear,"' "pea pod," "'manta ray," and "rose." One-third of the subjects did not recognize the picture of the calipers, and an additional eight did not know its name. Six percent of the responses were DKO and DKN responses. The failure rate in Snodgrass and Vanderwart is smaller, only $1.7 \%$, and most likely reflects the high degree of familiarity engendered by that picture set, which represents objects that are more common than those in Set 3. A small number of the alternative names given for Set 3 items are considered failures because they do not have any relationship to the concepts. Some examples of failures are "potato" for jellyfish and "garage" for harmonica.

The young children provided modal names that differed from those provided by adults for 28 of the pictures ( $35 \%$ of the concepts; see Table B1 in Appendix B, Items 322-400). One picture, that of an anvil, was not recognized by any child and therefore has no modal name for this age group. The other 27 pictures with different modal names include one synonym ('panda bear'" for panda), eight superordinates, and 11 coordinates. The modal name for the picture of the skull was "skeleton." In our analysis scheme this is considered a component name (part of). In addition, 6 pictures received modal names that are considered failures: "egg" for avocado, 'belt' for calipers, "clock" for compass, "wheel" for cymbal, "needle" for dart, and "bat"' for ray. In these failures, names of objects that are visually, and sometimes also semantically, similar to the concept are assigned by the children. The DKO and DKN categories account for $27 \%$ of the responses. The nondominant names provided by children and adults are presented, respectively, in Tables C1 (Items 322-400) and C2 of Appendix C.

Table 6 shows the summary statistics for both adults and young children for the 79 pictures. For the adults, the 79 concepts produced lower name agreement than did the Snodgrass and Vanderwart (1980) pictures, but Picture

Set 3 yielded higher name agreement than did the Berman et al. (1989) pictures (Set 2). However, the 79 pictures (of Set 3 ) were rated less familiar and visually more complex than the pictures in the other two sets. This result is consistent with the word frequency count, which, for the adults, has a mean of 7.54 occurrences per million in Set 3, much lower than that for the other two sets ( 37.17 for Set 1 , and 14.18 for Set 2 ). This may be due to the fact that Set 3 included a large number of less common animal pictures from the categories of mammals, birds, insects, and sea creatures. These concepts (e.g., armadillo, scorpion) were not as typical of their categories as those in the other two sets and were included because they had been used in our laboratory as fillers in a variety of memory tasks (e.g., Kazmerski \& Friedman, in press).

Although Set 3 includes pictures that are less familiar and more complex than pictures in Sets 1 and 2, for the adults only the familiarity measure correlates with name agreement (see Table 7, top). Naming latency shows substantial correlations with both measures of name agreement and with familiarity. This again supports the notion that more familiar pictures elicit a higher percentage of name agreement and faster naming latency.

As can be seen in Table 6, both measures of name agreement indicate significantly less agreement among the young children than among adults ( $p<.001$ ). The young children also rate the pictures as less familiar
than adults ( $p<.001$ ). However, both groups rate the visual complexity of the pictures similarly. Word length for young children's modal names is significantly shorter than that for adults ( $p<.005$ ), which again appears to reflect the fact that 6 -year-old children's vocabulary consists of short words. The correlations among the measures for the children are presented in Table 7 (bottom). As expected, the two measures of name agreement correlate with one another. In addition, naming latency correlates with each of the name agreement measures and also with visual complexity. Although adults show a significant correlation between familiarity and percentage name agreement, this correlation is not significant for the young children.

In summary, Picture Set 3 includes items that are less familiar to both adults and young children compared to Set 1 , which is reflected in lower name agreement measures. The young children, however, produced many more alternative names than the adults, resulting in a mean percentage of name agreement that does not even reach $50 \%$. Nevertheless, pictures from this set could be used when stimulus materials with low familiarity ratings are needed or when the study requires knowledge of the concept's category but not its name.

## Comparison of the Three Sets for the Young Children

Measures from each data set were compared against those from the other sets to determine whether inherent differences existed among the three picture sets. Differences in name agreement are most dramatic between Set 1 ( $H=$ $0.88, \%=72)$ and either Set $2(H=1.56, \%=48)$ or Set $3(H=1.71, \%$ $=43$ ). Results of two-tailed $t$ tests reveal significant differences between Set 1 and each of the other two sets for both measures of name agreement ( $p<$ .001 ). There is no significant difference between Set 2 and Set 3 .

Although the two measures of name agreement correlate, they reflect slightly different aspects of the data. The $H$ statistic represents the degree of variability among the names that are given to each concept. Sets 2 and 3 contain a relatively high percentage of concepts that elicit multiple names. Multiple names can exist for various reasons: (1) a concept can have more than one name, such as "gun,'" 'pistol," and 'revolver"' (2) the subject may name the pictures inaccurately; and (3) the drawing may not reflect accurately the concept it was intended to depict. An attempt was made to assess which of these alternatives may have produced name divergence in each of the three sets. The three sets do not differ in the percentage of synonym names (3.12, 5.03, and 3.08 for Sets 1, 2, and 3, respectively). The major difference is in the percentage of names that are considered failures, Set 1 having fewer failures ( $3.26 \%$ ) than Sets 2 and 3 ( 7.87 and $10.76 \%$, respectively). The percentage of name agreement takes into account DKO and DKN responses and therefore gives some indication of the recognizability of a picture by the subject. It is clear that Sets 2 and 3 include pictures that are unrecognized by a relatively large number of young
children compared to Set 1 . There are two possible reasons for the low recognition of the pictures by young children. One reason is that these pictures are less familiar, a fact that can be verified by the familiarity ratings and by the word frequency count. Comparing the familiarity ratings of the three sets reveals a significant difference between Sets 1 and 3 only ( $p<.001$ ). As mentioned previously, Set 3 includes unusual animals and other less common objects, such as an anvil, that are especially atypical in the children's experience. For some pictures, such as stethoscope, children were familiar with the concept yet they could not assign a correct name. Pictures in Sets 1 and 3 also differ in their word frequency counts for modal names assigned by adults $(p<.002)$. This is taken as additional evidence of a difference in familiarity between the pictures in these sets. There was no such difference between Sets 1 and 2. Thus, it seems that a difference in concept familiarity plays the largest role in accounting for the disparity in name agreement between Sets 1 and 3.

The second reason for the low values in percentage agreement is that complicated and detailed pictures are more difficult for children to identify. Examples of such pictures are the pinball machine, thermos, and headphones. Those concepts are not completely absent from the young children's environment, but their representation in the drawings may be relatively unclear. Supporting this notion, there was a significant difference between the ratings of visual complexity between Sets 1 and 2 only ( $p<.017$ ). Set 2 includes pictures from the PPVT-R (Peabody Picture Vocabulary TestRevised), some of which differ in drawing style from those appearing in Set 1 . Some of these pictures depict scenes containing background objects in addition to the main concept. For example, one picture shows a fern set against a background of a rock. For this picture, some children identified the rock rather than the fern.

The non-modal names that children provided for the pictures from Sets 2 and 3 are mostly of the coordinate and superordinate classes. The other classes-synonym, subordinate, and component-account for a smaller proportion of the alternative names. Thus, although there are more alternative names given to concepts in Sets 2 and 3 compared to Set 1, their distribution among the classes is similar across all sets.

As mentioned previously, the picture-naming process is assumed to involve at least three stages. In the first stage of object identification, only the physical description of the object is retrieved. In the second stage, name activation, the semantic features of the object are accessed, and in the response generation stage, the picture name is retrieved and pronounced. In an alternative model with four stages the name activation stage includes two separate representations, structural and semantic (Humphreys et al., 1988). The children's naming errors, which were mostly coordinates of and visually similar to the depicted objects, may have occurred during any of the three or, alternatively, the four stages. Children may have misidentified the objects depicted by the pictures (first stage), may have made seman-

TABLE 8
Factor Analysis of the Young Children's Data for Picture Sets 1, 2, and 3

| L | 0.29 | 0.82 | 0.12 | 0.03 | -0.72 | 0.31 | 0.03 | 0.80 | -0.06 |

Note. H, information statistic; \%, percentage of name agreement; F, familiarity; CO, visual complexity; L, word length of modal name; AH-3, word frequency.
tic errors by accessing the meaning (or name) of structurally and/or semantically similar objects (second stage or, alternatively, second and third stages in the four stage model), or may have been confused in searching for the names (third stage or, alternatively, fourth stage). When the alternative names are not coordinates, as in Johnson's (1992) study, then it is possible that naming errors reflect problems with the name activation and response generation stages, rather than the identification stage.

The relationship among the variables in each set can also provide evidence on the degree of similarity among the picture sets. To examine these relationships, factor analyses were performed and, for comparison purposes, the same procedures described by Berman et al. (1989) were followed. A three-factor solution with varimax rotation was generated using pairwise deletion of cases with missing data. For each picture set the factor analysis was performed with the picture as the unit of measurement ( 260 for Set 1, 61 for Set 2, and 79 for Set 3). Each picture was associated with the six variables described above, with each variable reflecting the mean score of the number of subjects that entered into the computation (a maximum of 30 subjects). Table 8 presents the factor loadings between each factor and the six variables that were used for the three sets for the data of the young children. As can be seen, for all sets, Factor 1 represents the contribution of the two measures of name agreement, whereas only Set 1 shows a contribution of familiarity. For all sets, the second factor represents the measures of word frequency and word length, which characterize the lexical aspects of the picture. In Sets 1 and 3, the third factor is dominated by a contribution from visual complexity with a smaller concept familiarity component. In addition, the loadings of visual complexity and familiarity were of opposite sign for Sets 1 and 3, which indicates that for these sets high familiarity ratings are associated with low visual complexity ratings. However, Set 2 revealed an equal (and same direction) contribution of familiarity and complexity to the third factor. This is consistent with the fact that the visual complexity ratings of Sets 1 and 3 and Set 2 differed (see above). As mentioned earlier, the pictures in Set 2 were taken from the PPVT-R, and their drawing style

TABLE 9
Factor Analysis of the Adult Data for Picture Set 3

|  | Set 3 |  |  |

is different (more detailed) than those in Sets 1 and 3 . Thus, for Set 2 , familiar concepts also tended to be rated as visually complex.

Although the three sets show a similar pattern of interaction among the variables, comparing these results to the factor analysis for adults reveals some differences. The factor loadings of the six variables for Set 3 of the adult data are presented in Table 9. As for the factor loadings of the young children (Table 8), Factor 1 represents the contribution from the name agreement measures. However, familiarity also contributes to this factor. Factor 2 shows a contribution primarily from the word-count measure ( $\mathrm{K}-\mathrm{F}$ ) and to a lesser extent from the familiarity measure. The third factor reflects the contribution of word length and visual complexity. These last two factors appear to load differently in the young children compared to the adults. It seems that the familiarity aspect of the picture in this set interacts with the name agreement measures for the adults but not for the young children.

In summary, measures of name agreement, familiarity, and visual complexity for young children differ among sets. Set 1 has the highest name agreement, Set 2 includes pictures that are more visually complex, and Set 3 contains pictures that are the least familiar. Nevertheless, factor analyses of each of the three sets yielded highly similar factor structures. For each set, the first factor shows a contribution from the name agreement measures, the second factor from the lexical aspects of the pictures, and the third factor from both the familiarity and the visual complexity measures. These data suggest that the impact of these measures on naming performance is similar across all three sets. Because no reliability data were collected in the present study, one might question the stability of the judgments of familiarity and visual complexity. However, as the factor analyses indicate, the interactions among the six variables were highly similar for the three picture sets. Moreover, the interactions among the six variables were highly similar for the young children
of this study when compared to the older children of Berman et al. (1989). These data thus provide some evidence for the consistency and the replicability of the measures.

## Significance of the Normative Data for Future Research

Based on their SES scores, the children who participated in the present study were mostly from middle class backgrounds, and thus the data presented should be useful in most studies with children. However, the data might not be applicable in research with children from more widespread socio-economic backgrounds.

The measures of name agreement, familiarity, and visual complexity are essentially independent and may be assumed to affect different stages during picture processing tasks. Thus, each should be considered in designing research studies involving pictures. For example, in studies where the task is to name the pictures, it is expected that children will incorrectly name pictures with low name agreement and familiarity (adults will be expected to show an increase in latency). The measure of familiarity in this case is similar to that of word frequency. In contrast, in studies of memory for pictures, performance will probably be affected by the visual complexity of the pictures. Consistent with this, Bevan and Steger (1971) reported superior recall for complex pictures compared to simple pictures. However, Pezdek and Chen (1982) found that recognition memory for simple pictures was better than for complex pictures.

These normative data have been used to choose pictures for a study of the development of implicit memory (Cycowicz \& Friedman, 1994). Implicit memory is exhibited by an increase in a subject's skill in processing a previously presented stimulus. In this study, children (ages 5-6 and 9-10), adolescents (ages 14-16), and young adults (ages 20-30) were recruited and implicit memory was assessed using a picture-fragment completion task. Subjects viewed a series of fragmented pictures in increasing degrees of completion and were asked to identify the concept by naming it. Cycowicz and Friedman (1994) were able to demonstrate an age-related increase in implicit memory performance. However, because pictorial concepts had been chosen based on the norms described here, Cycowicz and Friedman (1994) were better able to conclude that they had indeed demonstrated an agerelated improvement in implicit memory that was not simply due to the young children's lack of particular concepts in their semantic memory.

In summary, the present study shows that young children name pictures differently than older children and adults. There are also differences among the groups in their rating of picture familiarity and, to a lesser extent, in visual complexity. A large number of pictorial stimuli have been provided whose properties have been quantified for both adults and young children. It is expected that these norms will be useful in future developmental research involving pictorial processing across a wide age range.

## APPENDIX A

A total of 400 pictures, arranged in three sets, are shown with their identifying number. Set 1 is presented $1-260,{ }^{1}$ Set 2 is presented $261-321,{ }^{2}$ and Set 3 is presented $322-400$. Within each set the pictures are arranged alphabetically according to their intended name. The names for each picture and their norms are shown in Appendix B.

Note. Inten. name is the intended name for each concept; Modal name is the name given by the majority of subjects; $H$ statistic and percentage agreement (\%) are two measures of name agreement; Complexity is the visual complexity measure; $L$ is the number of letters in the modal name; K-F is the frequency count of the modal name, found in the Kucera-Francis corpus (1967), expressed as occurrences per million words. The (-) indicates that data are not available. Those modal names that differed from the intended names are printed in boldface.

## APPENDIX C

The following tables present subject responses other than the intended names for Picture Sets 1, 2, and 3 listed according to their presentation in Appendices A and B. Table C1 presents alternate responses of 5- to 7-year-old subjects, and Table C2 presents alternate responses of adult subjects for Set 3 .

TABLE C1<br>Nondominant Names Given by Young Children

| Item | Intended Name | DKO | DKN | Nondominant Names |
| :---: | :---: | :---: | :---: | :---: |
| 1. | accordion | 3 | 17 | saxophone (1) music* (1) piano (1) instrument (1) |
| 2. | airplane | 0 | 0 | plane (5) jet (1) |
| 3. | alligator | 0 | 0 | crocodile (9) lizard (2) dragon (1) |
| 4. | anchor | 9 | 2 | hook (6) |
| 5. | ant | 4 | 1 | bug (6) spider (4) |
| 6. | apple | 0 | 0 |  |
| 7. | arm | 0 | 0 | hand (15) finger (2) hand and wrist (1) |
| 8. | arrow | 0 | 0 |  |
| 9. | artichoke | 14 | 4 | $\begin{aligned} & \text { balloon }^{\dagger}(2) \text { bananas }^{\dagger}(1) \text { cabbages }(1) \text { fruit }^{\dagger}(1) \\ & \text { lettuce (1) palm } \operatorname{tree}^{\dagger}(1) \text { parachute }^{\dagger}(1) \text { tree }^{\dagger}(1) \\ & \text { vegetable (1) } \end{aligned}$ |
| 10. | ashtray | 24 | 0 | hole $^{\dagger}$ (3) magnify glass ${ }^{\dagger}$ (1) stethoscope ${ }^{\dagger}$ (1) to make shapes ${ }^{\dagger}$ (1) |
| 11. | asparagus | 11 | 3 | ```stick (3) branch (3) candle ( ) (2) chicken }\mp@subsup{}{}{\dagger}\mathrm{ (1) leaf (1)``` |
| 12. | axe | 3 | 2 | hammer (4) chopper (1) tomahawk (1) |
| 13. | baby carriage | 0 | 1 | carriage (20) stroller (4) baby cart (1) |
| 14. | ball | 0 | 0 |  |
| 15. | balloon | 0 | 0 |  |
| 16. | banana | 0 | 0 |  |
| 17. | barn | 2 | 0 | farm (8) house (4) farm house (2) barn house (1) cow house (1) toy ${ }^{\dagger}$ (1) |

Note. Alternate responses include 'don't know object'" (DKO), 'don't know name'" (DKN), as well as all names other than the intended name. Each item in the 'Nondominant Names"' column is followed by its number of occurrences. Those items whose modal name differed from the intended name are denoted with boldface, and the corresponding modal name (which appears first among the 'Nondominant Names'') is underlined. Failures to name are distinguished from other types of alternative responses by one of two superscripts. $\dagger$ Conceptual failure, i.e., the subject did not recognize the object or its category (e.g., response of "stethoscope"' for a picture of an ashtray). * Semantic failure, i.e., the subject recognized the object but failed to give an appropriate name. Inappropriate names include non-nouns (e.g., 'to fix stuff''), invented nouns (e.g., 'switch light,'" 'key locker''), abstract nouns (e.g., ''music'"), and associated nouns (e.g., "tea'" for the picture of a tea kettle).

| Item | Intended Name | DKO | DKN | Nondominant Names |
| :---: | :---: | :---: | :---: | :---: |
| 18. | barrel | 13 | 0 | basket (2) garbage can (2) box (1) |
| 19. | baseball bat | 0 | 2 | bat (22) |
| 20. | basket | 1 | 0 |  |
| 21. | bear | 2 | 0 | polar bear (4) |
| 22. | bed | 0 | 0 |  |
| 23. | bee | 0 | 0 | bumble bee (4) bug (4) spider (2) |
| 24. | beetle | 7 | 0 | bug (7) spider (5) ant (3) cockroach (2) cricket (1) fly (1) grasshopper (1) insect (1) |
| 25. | bell | 0 | 0 |  |
| 26. | belt | 1 | 0 | watch $^{\dagger}$ (3) collar (1) |
| 27. | bicycle | 0 | 0 | bike (7) |
| 28. | bird | 0 | 0 | ducky (1) little baby chick (1) pigeon (1) |
| 29. | blouse | 0 | 0 | shirt (13) jacket (11) coat (5) dress (1) |
| 30. | book | 0 | 0 |  |
| 31. | boot | 0 | 0 | shoe (1) |
| 32. | bottle | 0 | 0 | cup (1) glass of wine (1) wine* (1) wine bottle (1) |
| 33. | bow | 0 | 0 | bow tie (2) ribbon (1) tie (1) |
| 34. | bowl | 0 | 0 | cup (1) |
| 35. | box | 0 | 0 | little box (1) |
| 36. | bread | 0 | 0 | loaf of bread (1) piece of bread (1) slice of bread (1) |
| 37. | broom | 0 | 0 |  |
| 38 | brush | 0 | 0 | hairbrush (1) |
| 39. | bus | 0 | 0 | school bus (2) |
| 40. | butterfly | 0 | 0 |  |
| 41. | button | 0 | 0 | door $\mathrm{knob}^{\dagger}$ (1) wheel $^{\dagger}$ (1) |
| 42. | cake | 0 | 0 | piece of cake (1) |
| 43. | camel | 1 | 2 |  |
| 44. | candle | 0 | 0 | candle light (1) |
| 45. | cannon | 10 | 4 | gun (2) wheel (2) |

| 335. | can | 0 | 0 | open can (6) tin can (3) can of food (2) |
| 336. | cheese | 0 | 0 | swiss cheese (13) wedge of cheese (1) |
| 337. | cockroach | 0 | 2 | roach (7) beetle (5) bug (2) cricket (1) grasshopper (1) insect (1) |
| 338. | compass | 0 | 1 | stopwatch ${ }^{\dagger}(3)$ watch $^{\dagger}(1)$ |
| 339. | crab | 0 | 0 | lobster (1) sand crab (1) scorpion (1) |
| 340. | cymbals | 5 | 0 | barbell ${ }^{\dagger}$ (4) weights $^{\dagger}$ ( 3 ) castanets (1) door knob (1) dumbbell ${ }^{\dagger}$ (1) records $^{\dagger}(1)$ round blades $^{\dagger}(1)$ spool of thread ${ }^{\dagger}$ (1) |
| 341. | dart | 0 | 0 |  |

Note. Alternate responses include "don't know object'" (DKO), 'don't know name" (DKN), as well as all names other than the intended name. Each item in the "Nondominant Names" column is followed by its number of occurrences. Those items whose modal name differed from the intended name are denoted in boldface, and the corresponding modal name (which appears first among the 'Nondominant Names') is underlined. Failures to name are distinguished from other types of alternative responses by one of two superscripts. $\dagger$ Conceptual failure, i.e., the subject did not recognize the object or its category. * Semantic failure, i.e., the subject recognized the object but failed to give an appropriate name.

| Item | Intended Name | DKO | DKN | Nondominant Names |
| :---: | :---: | :---: | :---: | :---: |
| 342. | dinosaur | 0 | 0 | ```tyrannosaurus rex (4) tyrannosaurus* (1) rex* (1)``` |

| 377. | ray | 4 | 4 | manta ray (8) stingray (7) bat $^{\dagger}$ (1) man-o-war (1) manta ray eel* (1) praying mantis ${ }^{\dagger}(1)$ sea urchin (1) squid (1) |
| 378. | rosebud | 0 | 0 | rose (14) branch (2) flower (2) tulip (1) |
| 379. | saxophone | 0 | 0 | trumpet (2) horn (1) sax (1) |

TABLE C2—Continued

| Item | Intended Name | DKO | DKN | Nondominant Names |
| :---: | :---: | :---: | :---: | :---: |
| 380. | scorpion | 0 | 3 | lobster ${ }^{\dagger}$ (8) $\mathrm{crab}^{\dagger}$ (1) crayfish (1) |
| 381. | shark | 0 | 0 | fish (1) whale (1) |
| 382. | skeleton | 0 | 0 | human skeleton (7) |
| 383. | skull | 0 | 1 | human skull (4) skeleton (1) skeleton head (1) |
| 384. | spatula | 0 | 4 | aluminum spatula (1) |
| 385. | spider web | 0 | 0 | web (9) spider's web (4) |
| 386. | squash | 5 | 3 | gourd (7) balloon ${ }^{\dagger}$ (1) discarded enema ${ }^{\dagger}$ (1) papaya ${ }^{\dagger}$ (1) squash gourd (1) |
| 387. | starfish | 0 | 0 |  |
| 388. | stethoscope | 0 | 6 |  |
| 389. | swordfish | 2 | 1 | shark (2) marlin (1) saw fish * (1) |
| 390. | thermometer | 0 | 0 | thermostat (1) |
| 391. | totem pole | 0 | 1 | Eskimo totem (1) idol (1) |
| 392. | toucan | 0 | 2 | parrot (7) pelican (3) bird (1) relative of the dude on commercial (1) toucan sam (1) |
| 393. | turkey | 0 | 0 | rooster (1) |
| 394. | vulture | 0 | 1 | bald eagle (3) eagle (3) bird (1) |
| 395. | walrus | 1 | 0 | sea lion (1) |
| 396. | washing machine | 0 | 0 | clothes washer (2) laundry machine (1) open washing machine (1) washer (1) |
| 397. | whale | 1 | 0 | humpback (2) porpoise (2) sperm whale (2) blue whale (1) |
| 398. | whip | 3 | 0 | bull whip (1) horse whip (1) |
| 399. | wolf | 0 | 0 | coyote (3) fox (1) |
| 400. | worm | 2 | 0 | earthworm (11) snail (2) larvae (1) $\mathrm{hom}^{\dagger}$ (1) |

## APPENDIX D

The 13 Categories with Their Exemplars

| Four-footed animals | Alligator, Bear, Camel, Cat, Cow, Deer, Dog, Donkey, Elephant, Fox, Frog, Rabbit, Raccoon, Rhinoceros, Sheep, Skunk, Squirrel, Tiger, Turtle, Zebra |
| :---: | :---: |
| Basic level | Bird, Fish, Flower, Tree |
| Birds | Chicken, Duck, Eagle, Ostrich, Owl, Peacock, Penguin, Rooster, Swan |
| Clothing | Belt, Blouse, Boot, Button, Cap, Coat, Crown, Dress, Glove, Hat, Jacket, Mitten, Necklace, Pants, Pocketbook, Ring, Shirt, Shoe, Skirt, Sock, Sweater, Tie, Vest, Watch |
| Fruits | Apple, Banana, Cherry, Grapes, Lemon, Orange, Peach, Pear, Pineapple, Strawberry, Watermelon |
| Furniture | Ashtray, Bed, Chair, Clock, Couch, Desk, Dresser, Lamp, Record player, Rocking chair, Stool, Table, Television, Vase |
| Human body parts | Arm, Ear, Eye, Finger, Foot, Hair, Hand, Leg, Lips, Nose, Thumb, Toe |
| Insects | Ant, Bee, Beetle, Butterfly, Caterpillar, Fly, Grasshopper, Snail, Snake, Spider |
| Kitchen utensils | Bottle, Bowl, Broom, Cup, Fork, Frying pan, Garbage can, Glass, Kettle, Knife, Pitcher, Pot, Refrigerator, Rolling pin, Salt shaker, Spoon, Stove, Toaster, Wine glass |
| Musical instruments | Accordion, Bell, Drum, Flute, French horn, Guitar, Harp, Piano, Trumpet, Violin |
| Tools | Axe, Chisel, Hammer, Ladder, Nail, Nut, Pliers, Saw, Screw, Screwdriver, Wrench |
| Toys | Ball, Balloon, Baseball bat, Doll, Kite, Snowman, Swing, Top, Whistle |
| Vegetables | Artichoke, Asparagus, Carrot, Celery, Corn, Lettuce, Mushroom, Onion, Peanut, Pepper, Potato, Pumpkin, Tomato |
| Vehicles | Airplane, Baby carriage, Bicycle, Bus, Car, Helicopter, Motorcycle, Roller skate, Sailboat, Sled, Train, Truck, Wagon |
