Dedicated with respect and affection to Gerry Pattenden, an inspiring scientist, on the occasion of his 70<sup>th</sup> birthday

**Abstract:** A convenient, asymmetric synthesis of (*R*)-homopipelic acid methyl ester and an homochiral peptide nucleic acid (PNA) monomer building block are described, starting from the orthogonally disubstituted (2*E*,7*E*)-nonadienedioate. The approach involves stereoselective Michael monoaddition of (*R*)-*N*-benzyl-*N*- $\alpha$ -methylbenzylamide to the unsaturated ester as the key step, and subsequent transformation of the remaining double bond of the unsaturated acid.

**Key words:**  $\beta$ -amino acids, asymmetric synthesis, Michael additions, PNA, homopipelic acid, orthogonally substituted dienedioate

Every synthetic route starts from a particular substrate that lends itself to the retrosynthetic scheme planned. The capacity of a substrate to participate in a wide range of synthetic pathways depends on the potential of their structure: cycles, chains and functional groups. Molecules with functional groups that react selectively are attractive from this point of view: the better the chemical orthogonality of the functional groups, the larger the spectrum of synthetic transformations possible and, consequently, the range of accessible targets.

Cyclic  $\beta$ -amino acids such as (*R*)-homopipelic acid (Scheme 1) have a number of interesting features that have been used to develop synthons of natural products<sup>1</sup>

and key intermediates in  $\beta$ -lactam structures.<sup>2</sup> Synthetic oligonucleotides (Scheme 1; DNA/RNA) have been considered as potential gene-targeted therapeutic agents (antisense and antigene).<sup>3</sup> Peptide nucleic acids (PNAs) were first reported in 1991 as DNA mimics<sup>3c</sup> and, since this time, a vast number of studies have been reported covering their synthesis, properties and potential applications. Among the known oligonucleotide analogues, acyclic *N*-(2-aminoethyl)glycyl peptide nucleic acids (Scheme 1; PNA I) or those derived from base-containing  $\delta$ -amino acid derivatives<sup>4</sup> (Scheme 1; PNA II), are found to be very good mimics of DNA/RNA. Within this area, a steadily growing group of analogues in which the sugar-phosphate backbone is replaced by a polyamide backbone, is emerging, mainly as a consequence of the intriguing base-pairing properties of their prototype PNA. In this context, we envisaged the synthesis of the amino acid building block monomer **2** in PNA III.

We have demonstrated<sup>5</sup> the use of chiral lithium ( $\alpha$ -methylbenzyl)benzylamide [(*R*)-**3** or (*S*)-**3**] to initiate asymmetric conjugate addition cyclisation of octa-2,6-dienedioate and nona-2,7-dienedioate to generate chiral cyclopentane and cyclohexane derivatives **4** and **5**, respectively.<sup>5b-c</sup> We have also developed strategies to stereoselectively obtain double- (**7**) and mono-addition (**6**, **8**, **9** and **10**) products<sup>5d</sup> (Scheme 2), where the *Z*-double bond

Scheme 1

plays a crucial role on the (*Z,E*)-dienedioate as a vehicle for  $\gamma$ -deprotonation. We have proposed **9** to be an intermediate in an approach to **1**.<sup>5a</sup>

Here, as shown in the retrosynthetic analysis (Scheme 3), we focused on the potential of (*2E,7E*)-nonadienedioate **11** as an orthogonally functionalised starting material in which the groups show differing reactivity towards lithium (*R*)-*N*-benzyl-*N*- $\alpha$ -methylbenzylamide [(*R*)-**3**]. This selectivity is exploited synthetically by modifying the residual functionality to give either homopipecolic acid methyl ester (formerly synthesised using other protocols<sup>6</sup>) or to construct a thymine long-chain  $\beta$ -amino acid PNA monomer **2** for use in oligomerisation to form PNA. Both goals were developed in an enantiocontrolled way.

**Scheme 2** Reagents and conditions: (a) (*R*)-**3** (1.2 equiv), THF,  $-78\text{ }^{\circ}\text{C}$ ; (b) (*R*)-**3** (3 equiv), THF,  $-78\text{ }^{\circ}\text{C}$ ; (c) *t*-BuOK, *t*-BuOH.

The synthesis of homopipecolic methyl ester (Scheme 4) started with addition of lithium (*R*)-*N*-benzyl-*N*- $\alpha$ -methylbenzylamide [(*R*)-**3**] to the orthogonally functionalised substrate **11**, to provide adduct **12** (de >95%)<sup>7</sup> stereoselectively (*vide infra*) in good yield, in accordance with the literature.<sup>8</sup> Acid salt generation enriches electron-density on the conjugated olefin, averting nucleophilic attack at this centre. The next step required ozonolysis of **12**, however, since reports in the literature recommended prior esterification,<sup>9</sup> **12** was treated with TMSCHN<sub>2</sub> to provide the corresponding diester **13**.<sup>10</sup> Attempts at ozonolysis of **13** were unsuccessful, leading instead to decomposition of the starting material as a consequence of *N*-oxide

**Scheme 3** Proposed strategy for the synthesis of (*R*)-homopipecolic acid and monomers **1** and **2** for PNA synthesis

formation<sup>11</sup> provoking a Cope elimination. However, treatment of **13** with anhydrous HCl followed by ozonolysis and reduction with Me<sub>2</sub>S gave aldehyde **15**. Finally, hydrogenolytic debenzoylation over Pearlmans catalyst induced cyclisation to the imine, which underwent reduction to (*R*)-homopipecolic methyl ester in situ {[ $\alpha$ ]<sub>D</sub><sup>26</sup>  $-3.6$  (*c* 0.32, CHCl<sub>3</sub>); Lit.<sup>6c</sup> for the enantiomer [ $\alpha$ ]<sub>D</sub><sup>26</sup>  $+3.9$  (*c* 0.64, CHCl<sub>3</sub>)} in 50% overall yield.

**Scheme 4** Reagents and conditions: (a) Lithium (*R*)-*N*-benzyl-*N*- $\alpha$ -methylbenzylamide [(*R*)-**3**; 3.6 equiv], THF,  $-78\text{ }^{\circ}\text{C}$ ; (b) TMSCHN<sub>2</sub>, benzene–MeOH (1:1), 30 min; (c) HCl (g); (d) O<sub>3</sub>, then Me<sub>2</sub>S; (e) Pd(OH)<sub>2</sub>/C, H<sub>2</sub> (4 atm), EtOAc.

**Scheme 5** Reagents and conditions: (a) Pd(OH)<sub>2</sub>/C, H<sub>2</sub> (4 atm), Boc<sub>2</sub>O, EtOAc, 3 d; (b) BH<sub>3</sub>·THF, THF, 20 °C, 60 min; (c) CBr<sub>4</sub>, Ph<sub>3</sub>P, CH<sub>2</sub>Cl<sub>2</sub>, 45 min; (d) thymine, TBAI, K<sub>2</sub>CO<sub>3</sub>, DMF, 70 °C, 6 h.

The route towards the PNA monomer started from **12** (Scheme 5). Reacting a mixture of **12**, Boc<sub>2</sub>O and Pearlman's catalyst in ethyl acetate for three days under hydrogen (4 atm), accomplished a one-pot amine-debenzylation, Boc-reprotection and hydrogenation of the olefin in 62% yield. Subsequent selective reduction of the carboxylic acid with borane, followed by treatment with CBr<sub>4</sub>/PPh<sub>3</sub>, and finally, treatment with thymine, K<sub>2</sub>CO<sub>3</sub>, and TBAI in refluxing DMF<sup>12</sup> provided the target compound **2**.<sup>13</sup> However, the poor nucleophilicity of thymine resulted in a relatively low yield in the final displacement (38%).

In summary, we have achieved the synthesis of two valuable products as important building blocks: (*R*)-homopipicolic methyl ester and a PNA-monomer containing a long-chain β-amino acid backbone. Both products were elaborated in a divergent fashion starting from (2*E*,7*E*)-nonadienedioate monoester **11**, which is a readily accessible bifunctional substrate that exhibits orthogonal behaviour towards aza-Michael stereocontrolled addition of chiral lithium (*α*-methylbenzyl)benzylamide. The residual functionality can then undergo a range of possible synthetic transformations, demonstrating the power of this protocol.

### Acknowledgment

The authors are grateful for financial support from the Spanish MICINN (EUI2008-00173), MEC (CTQ2009-11172/BQU), the FSE and Junta de Castilla y León (Spain): (SA001A09) and excellence GR-178. The authors also thank Dr. A. M. Lithgow for work on the NMR spectra and Dr. César Raposo for the mass spectra. C.N. thanks Junta de Castilla y León for a FPI doctoral fellowship.
