

# ANY RITZ VALUE BEHAVIOR IS POSSIBLE FOR ARNOLDI AND FOR GMRES

JURJEN DUINTJER TEBBENS\* AND GÉRARD MEURANT†

**Abstract.** We show that arbitrary convergence behavior of Ritz values is possible in the Arnoldi method and we give two parametrizations of the class of matrices with initial Arnoldi vectors that generates prescribed Ritz values (in all iterations). The second parametrization enables us to prove that any GMRES residual norm history is possible with any prescribed Ritz values (in all iterations), provided we treat the stagnation case appropriately.

**Key words.** Ritz values, Arnoldi process, Arnoldi method, GMRES method, prescribed convergence, interlacing properties

**AMS subject classifications.** 65F15,65F10,65F18,15A18

**1. Introduction.** Let  $A$  be a nonsingular matrix of order  $n$  and  $b$  a nonzero  $n$ -dimensional vector. The Arnoldi process [3] reduces  $A$  to upper Hessenberg form by a particular type of Gram-Schmidt orthogonalization for the vectors  $b, Ab, A^2b, \dots$ . At each step of the process, one matrix-vector multiplication with  $A$  is performed and one row and one column is appended to the previous Hessenberg matrix. The process is well suited to iterative methods with large sparse matrices  $A$ . Two popular methods extracting approximate solutions from the generated Hessenberg matrices are the Generalized Minimal Residual (GMRES) method [39] for solving the linear system  $Ax = b$  and the Arnoldi method (see, e.g., [37, 38]) for computing the eigenvalues and eigenvectors of  $A$ .

The Arnoldi process can be seen as a generalization to non-hermitian matrices of the Lanczos process for tridiagonalization of hermitian matrices [22]. The Lanczos process is at the basis of the Conjugate Gradients (CG) method [21, 23] for hermitian positive definite linear systems and of the Lanczos method for hermitian eigenproblems [22]. In this sense GMRES is a generalization of CG (even though the  $l_2$  norm of the residual is not minimized in CG) and the Arnoldi method a generalization of the Lanczos method. As convergence of the CG and Lanczos methods are well understood, it was natural to take the convergence theory of these methods as a starting point for explaining the behavior of the GMRES and Arnoldi methods. In the CG method, the convergence behavior is dictated by the distribution of the eigenvalues of the matrix. In practice, the same is often observed for the GMRES method, but, with possibly non-normal input matrices, the situation becomes more subtle. For example, Greenbaum and Strakoš [20] proved that if a residual norm convergence curve is generated by GMRES, the same curve can be obtained with a matrix having prescribed nonzero eigenvalues (see [10, Lemma 6.9] for an analogue on prescribed nonzero singular values). Greenbaum, Pták and Strakoš [19] complemented their result by proving that *any* nonincreasing sequence of residual norms can be given by GMRES (a similar result for residual norms at the end of restart cycles in the restarted GMRES method can be found in [46]). Furthermore, in Arioli, Pták and Strakoš [2] a complete parametrization was given of all pairs  $\{A, b\}$  generating a prescribed residual norm convergence curve and such that  $A$  has prescribed spectrum. The results in these papers show that the GMRES residual norm convergence needs not, in general, depend on the eigenvalues of  $A$  alone. Other objects, mostly closely related to eigenvalues, have been considered to explain convergence, for example

the pseudo-spectrum [43], the field of values [9] or the numerical polynomial hull [18]. In [45] it was suggested that convergence of the eigenvalues of the Hessenberg matrices generated in the Arnoldi process (the so-called Ritz values) to eigenvalues of  $A$  will often explain the acceleration of convergence of GMRES.

A fundamental tool in the convergence analysis of the Lanczos method for hermitian eigenproblems is the interlacing property for the eigenvalues of the subsequently generated tridiagonal matrices. It enables to prove, among others, the persistence theorem on stabilization of Ritz values (see, e.g., [31, 32, 33] or [29]). There are several generalizations of the interlacing property to normal matrices; see e.g. [14, 1], or the papers [25, 12] with geometric interpretations. However, just as for GMRES, potentially non-normal input matrices make convergence analysis of the Arnoldi method delicate. There is no interlacing property for the principal submatrices of general non-normal matrices, see [41] for a thorough discussion on this topic and its relation to the field of Lie algebra's. In [30] one finds a sufficient and necessary condition for prescribing arbitrary eigenvalues of (not necessarily principal) submatrices of general non-hermitian matrices. For a detailed spectral analysis of non-normal Hessenberg matrices and their principal submatrices, see also [48].

Since the GMRES and the Arnoldi methods are closely related through the Arnoldi orthogonalization process, a naturally arising question is whether a result, similar to the results of Arioli, Greenbaum, Pták and Strakoš, on arbitrary convergence behavior of the Arnoldi method can be proved. By arbitrary convergence behavior of the Arnoldi method, we mean the ability to prescribe *all* Ritz values from the very first until the very last iteration (we do not consider convergence to eigenvectors). In this paper we will give a parametrization of the class of all matrices and initial Arnoldi vectors that generates prescribed Ritz values. Besides this result on arbitrary convergence behavior of the Arnoldi method, we derive a parametrization that allows to characterize all pairs  $\{A, b\}$  generating arbitrary convergence behavior of *both* GMRES and Arnoldi. The Ritz values generated in the GMRES method therefore do not, in general, have any influence on the generated residual norms.

The paper is organized as follows: In the remainder of this section we introduce some notation, in particular the notation used in [2], which we adopt and we recall the parametrization given in [2]. In Section 2 we give a parametrization of the class of matrices and initial Arnoldi vectors that generates prescribed Ritz values. Section 3 reformulates the parametrization in order to parametrize the pairs  $\{A, b\}$  generating arbitrary behavior of GMRES and Arnoldi at the same time. We close with a brief discussion of our results and some words on future work.

**1.1. Notation.** We will use the following parametrization of matrices and right-hand sides giving prescribed spectrum and prescribed convergence of the GMRES method (see Theorem 2.1 and Corollary 2.4 of [2]).

**THEOREM 1.1.** *Assume we are given  $n$  positive numbers*

$$f(0) \geq f(1) \geq \dots \geq f(n-1) > 0$$

*and  $n$  complex numbers  $\lambda_1, \dots, \lambda_n$  all different from 0. Let  $A$  be a matrix of order  $n$  and  $b$  an  $n$ -dimensional vector. The following assertions are equivalent:*

1. *The spectrum of  $A$  is  $\{\lambda_1, \dots, \lambda_n\}$  and GMRES applied to  $A$  and  $b$  with zero initial guess yields residuals  $r^{(k)}$ ,  $k = 0, \dots, n-1$  such that*

$$\|r^{(k)}\| = f(k), \quad k = 0, \dots, n-1.$$

2. *The matrix  $A$  is of the form*

$$A = WY C^{(n)} Y^{-1} W^*$$

and  $b = Wh$ , where  $W$  is a unitary matrix,  $Y$  is given by

$$(1.1) \quad Y = \begin{bmatrix} h & R \\ & 0 \end{bmatrix},$$

$R$  being a nonsingular upper triangular matrix of order  $n - 1$ ,  $h$  a vector such that

$$(1.2) \quad h = [\eta_1, \dots, \eta_n]^T, \quad \eta_k = (f(k-1)^2 - f(k)^2)^{1/2}, \quad k < n, \quad \eta_n = f(n-1),$$

and  $C^{(n)}$  is the companion matrix corresponding to the polynomial  $q(\lambda)$  defined as

$$q(\lambda) = (\lambda - \lambda_1) \cdots (\lambda - \lambda_n) = \lambda^n + \sum_{j=0}^{n-1} \alpha_j \lambda^j, \quad C^{(n)} = \begin{bmatrix} 0 & -\alpha_0 \\ I_{n-1} & \vdots \\ & -\alpha_{n-1} \end{bmatrix}.$$

Furthermore, we will denote by  $e_j$  the  $j$ th column of the identity matrix of appropriate order. For a matrix  $M$ , the leading principal submatrix of order  $k$  will be denoted by  $M_k$ . With “the subdiagonal” and “subdiagonal entries” we will mean the (entries on the) first diagonal under the main diagonal. Throughout the paper we assume exact arithmetics and we also assume that the investigated Arnoldi processes do not terminate before the  $n$ th iteration. This means that the input matrix must be nonderogatory. Note that Theorem 1.1 assumes this situation. The case of early termination will be treated in a forthcoming paper.

**2. Prescribed convergence of Ritz values in Arnoldi’s method.** Consider the  $k$ th iteration of an Arnoldi process with a matrix  $A$  and initial vector  $b$  where an upper Hessenberg matrix  $H_k$  (with entries  $h_{i,j}$ ) is generated satisfying

$$(2.1) \quad AV^{(k)} = V^{(k)}H_k + h_{k+1,k} v_{k+1} e_k^T, \quad k < n,$$

with  $V^{(k)*}V^{(k)} = I_k$ ,  $V^{(k)}e_1 = b/\|b\|$  and  $V^{(k)*}v_{k+1} = 0$ ,  $V^{(k)}$  being the matrix whose columns are the basis vectors  $v_1, \dots, v_k$  of the  $k$ th Krylov subspace  $\mathcal{K}_k(A, b) \equiv \text{span}\{b, Ab, \dots, A^{k-1}b\}$ . The eigenvalues of  $H_k$  give the  $k$ -tuple

$$\mathcal{R}^{(k)} = (\rho_1^{(k)}, \dots, \rho_k^{(k)})$$

of the  $k$  (not necessarily distinct) Ritz values generated at the  $k$ th iteration of Arnoldi’s method. We denote by  $\mathcal{R}$  the set

$$\mathcal{R} \equiv \{\mathcal{R}^{(1)}, \mathcal{R}^{(2)}, \dots, \mathcal{R}^{(n)}\}$$

representing all  $(n+1)n/2$  generated Ritz values. We also use  $\mathcal{S}$  for the *strict* Ritz values without the spectrum of  $A$ , i.e.

$$\mathcal{S} \equiv \mathcal{R} \setminus \mathcal{R}^{(n)},$$

and we will denote the (not necessarily distinct) eigenvalues of the input matrix by  $\lambda_1, \dots, \lambda_n$ , i.e.

$$\mathcal{R}^{(n)} = (\lambda_1, \dots, \lambda_n).$$

In this section we investigate whether the Arnoldi method can generate arbitrary Ritz values in all iterations. The Ritz values in the Arnoldi method are eigenvalues of the leading principal submatrices of upper Hessenberg matrices with positive real subdiagonal entries. Prescribing the set  $\mathcal{R}$  is only possible if there exist, at all, Hessenberg matrices with positive subdiagonal entries

where the eigenvalues of all the leading principal submatrices can be prescribed. Parlett and Strang proved that there is a unique upper Hessenberg matrix with the entry one along the subdiagonal such that all leading principal submatrices have arbitrary prescribed eigenvalues, see [35, Theorem 3]. We here give a characterization of this unique matrix, which we denote with  $H(\mathcal{R})$ , that shows how it is constructed from the prescribed Ritz values.

PROPOSITION 2.1. *Let the set*

$$\mathcal{R} = \{ \rho_1^{(1)}, \\ (\rho_1^{(2)}, \rho_2^{(2)}), \\ \vdots \\ (\rho_1^{(n-1)}, \dots, \rho_{n-1}^{(n-1)}), \\ (\lambda_1, \dots, \lambda_n) \},$$

represent any choice of  $n(n+1)/2$  complex Ritz values and denote the  $k \times k$  companion matrix of the polynomial with roots  $\rho_1^{(k)}, \dots, \rho_k^{(k)}$  by  $C^{(k)}$ . If we define the  $k$ th column of the unit upper triangular matrix  $U(\mathcal{S})$  through

$$(2.2) \quad U(\mathcal{S})e_1 = e_1, \quad U(\mathcal{S})e_k = \begin{bmatrix} -e_1^T C^{(k-1)} e_{k-1} \\ \vdots \\ -e_{k-1}^T C^{(k-1)} e_{k-1} \\ 1 \\ 0 \\ \vdots \end{bmatrix}, \quad k = 2, \dots, n,$$

then the unique upper Hessenberg matrix  $H(\mathcal{R})$  with the entry one along the subdiagonal and with the spectrum  $\lambda_1, \dots, \lambda_n$  such that the  $k$ th leading principal submatrix has eigenvalues  $\rho_1^{(k)}, \dots, \rho_k^{(k)}$  for all  $k = 1, \dots, n-1$  is

$$(2.3) \quad H(\mathcal{R}) = U(\mathcal{S})^{-1} C^{(n)} U(\mathcal{S}).$$

*Proof.* We will show that the spectrum of the  $k \times k$  leading principal submatrix of  $H(\mathcal{R})$  is  $\rho_1^{(k)}, \dots, \rho_k^{(k)}$  (uniqueness of  $H(\mathcal{R})$  was shown in [35] and will also be proved later). Let  $U_k$  denote the  $k \times k$  leading principal submatrix of  $U(\mathcal{S})$  and let, for  $j > k$ ,  $\tilde{u}_j$  denote the vector of the first  $k$  entries of the  $j$ th column of  $U(\mathcal{S})^{-1}$ . The spectrum of the  $k \times k$  leading principal submatrix of  $H(\mathcal{R})$  is the spectrum of

$$[I_k, 0] U(\mathcal{S})^{-1} C^{(n)} U(\mathcal{S}) \begin{bmatrix} I_k \\ 0 \end{bmatrix} = [U_k^{-1}, \tilde{u}_{k+1}, \dots, \tilde{u}_n] \begin{bmatrix} 0 \\ U_k \\ 0 \end{bmatrix} = [U_k^{-1}, \tilde{u}_{k+1}] \begin{bmatrix} 0 \\ U_k \end{bmatrix}.$$

It is also the spectrum of the matrix

$$U_k [U_k^{-1}, \tilde{u}_{k+1}] \begin{bmatrix} 0 \\ U_k \end{bmatrix} U_k^{-1} = [I_k, U_k \tilde{u}_{k+1}] \begin{bmatrix} 0 \\ I_k \end{bmatrix},$$

which is a companion matrix with last column  $U_k \tilde{u}_{k+1}$ . From

$$e_{k+1} = U_{k+1} U_{k+1}^{-1} e_{k+1} = \begin{bmatrix} U_k & -C^{(k)} e_k \\ 0 & 1 \end{bmatrix} \begin{bmatrix} U_k^{-1} & \tilde{u}_{k+1} \\ 0 & 1 \end{bmatrix} e_{k+1} = \begin{bmatrix} U_k \tilde{u}_{k+1} - C^{(k)} e_k \\ 1 \end{bmatrix}$$

we obtain  $U_k \tilde{u}_{k+1} = C^{(k)} e_k$ .  $\square$

Note that (2.3) represents a similarity transformation separating the spectrum of  $H(\mathcal{R})$  from the strict Ritz values  $\mathcal{S}$  of  $H(\mathcal{R})$ . The matrix  $U(\mathcal{S})$  transforms the companion matrix whose strict Ritz values are all zero to a Hessenberg matrix with arbitrary Ritz values and it is itself composed of (parts of) companion matrices. We will call  $U(\mathcal{S})$ , for lack of a better name, the *Ritz value companion transform*.

Clearly, the Ritz values generated in the Arnoldi method can exhibit any convergence behavior: It suffices to apply the Arnoldi process with the initial Arnoldi vector  $e_1$  and the matrix  $H(\mathcal{R})$  with arbitrary prescribed Ritz values from Proposition 2.1. Then the method generates the Hessenberg matrix  $H(\mathcal{R})$  itself. If the prescribed Ritz values occur in complex conjugate pairs, then the Ritz value companion transform  $U(\mathcal{S})$  and the Hessenberg matrix  $H(\mathcal{R})$  in (2.3) are real and the Arnoldi process runs without complex arithmetics.

We next look for a parametrization of the class of all matrices and initial Arnoldi vectors generating given Ritz values. From  $H(\mathcal{R})$  we can easily obtain an upper Hessenberg matrix whose leading principal submatrices have the same prescribed eigenvalues but with arbitrary positive values along the subdiagonal. Let  $\sigma_1, \sigma_2, \dots, \sigma_{n-1}$  be given positive real numbers and consider the similarity transformation

$$H \equiv \text{diag}(1, \sigma_1, \sigma_1 \sigma_2, \dots, \prod_{j=1}^{n-1} \sigma_j) H(\mathcal{R}) (\text{diag}(1, \sigma_1, \sigma_1 \sigma_2, \dots, \prod_{j=1}^{n-1} \sigma_j))^{-1}.$$

Then the subdiagonal of  $H$  has the entries  $\sigma_1, \sigma_2, \dots, \sigma_{n-1}$  and all leading principal submatrices of  $H$  are similar to the corresponding leading principal submatrices of  $H(\mathcal{R})$ . The following theorem shows the uniqueness of  $H$ .

**THEOREM 2.2.** *Let the set*

$$\mathcal{R} = \left\{ \begin{array}{l} \rho_1^{(1)}, \\ (\rho_1^{(2)}, \rho_2^{(2)}), \\ \vdots \\ (\rho_1^{(n-1)}, \dots, \rho_{n-1}^{(n-1)}), \\ (\lambda_1, \dots, \lambda_n) \end{array} \right\},$$

represent any choice of  $n(n+1)/2$  complex Ritz values and let

$$D_\sigma = \text{diag}(1, \sigma_1, \sigma_1 \sigma_2, \dots, \prod_{j=1}^{n-1} \sigma_j)$$

where  $\sigma_1, \sigma_2, \dots, \sigma_{n-1}$  are  $n-1$  positive real numbers. Then

$$H = D_\sigma H(\mathcal{R}) D_\sigma^{-1}$$

is the unique Hessenberg matrix  $H$  with subdiagonal entries

$$h_{k+1,k} = \sigma_k, \quad k = 1, \dots, n-1,$$

with eigenvalues  $\lambda_1, \dots, \lambda_n$  and with  $\rho_1^{(k)}, \dots, \rho_k^{(k)}$  being the eigenvalues of its  $k$ th leading principal submatrix for all  $k = 1, \dots, n-1$ .

*Proof.* We already explained that  $H$  has the desired Ritz values and subdiagonal entries. It remains to show uniqueness. For this we need a recursion for the characteristic polynomials of the

leading submatrices  $H_k$  of  $H$ . We denote the prescribed characteristic polynomial of  $H_k$  by  $p_k(\lambda)$  and by  $\sigma^{k,i}$  we denote the product of prescribed subdiagonal entries

$$\sigma^{k,i} = \prod_{\ell=i}^k \sigma_\ell.$$

We also define the polynomial  $p_0(\lambda) \equiv 1$ . Using expansion along the last column to compute the determinant of  $H_k - \lambda I$ , we get

$$\begin{aligned} \det(H_k - \lambda I) &= (-1)^{k-1} h_{1,k} \sigma^{k-1,1} + (-1)^{k-2} h_{2,k} p_1(\lambda) \sigma^{k-1,2} \\ &\quad + (-1)^{k-3} h_{3,k} p_2(\lambda) \sigma^{k-1,3} + \dots + (h_{k,k} - \lambda) p_{k-1}(\lambda), \end{aligned}$$

and hence we have the recursion

$$(2.4) \quad p_k(\lambda) = (h_{kk} - \lambda) p_{k-1}(\lambda) + \sum_{i=1}^{k-1} (-1)^{k-i} h_{ik} \sigma^{k-1,i} p_{i-1}(\lambda), \quad 1 \leq k \leq n.$$

Now assume both  $H$  and  $\tilde{H}$  have the desired Ritz values and subdiagonal entries and let us prove that  $H = \tilde{H}$  by induction for all subsequent leading principal submatrices. Clearly,  $h_{1,1} = \tilde{h}_{1,1} = \rho_1^{(1)}$  and if the claim is valid for all leading principal submatrices of dimension at most  $k-1$ , then the entries of  $H_k$  and  $\tilde{H}_k$  can differ only in the last column. By comparing the coefficients (subsequently before  $\lambda^k$  until  $\lambda^0$ ) of the polynomial  $p_k(\lambda)$  as given in (2.4) with the coefficients given by

$$p_k(\lambda) = (\tilde{h}_{kk} - \lambda) p_{k-1}(\lambda) + \sum_{i=1}^{k-1} (-1)^{k-i} \tilde{h}_{ik} \sigma^{k-1,i} p_{i-1}(\lambda),$$

we obtain  $h_{ik} = \tilde{h}_{ik}$  subsequently for  $i = k, k-1, \dots, 1$ .  $\square$

Theorem 2.2 immediately leads to a parametrization of the matrices and initial Arnoldi vectors that generate a given set of Ritz values  $\mathcal{R}$ . In addition, the subdiagonal of the generated Hessenberg matrix can be prescribed.

**COROLLARY 2.3.** *Assume we are given a set of tuples of complex numbers*

$$\begin{aligned} \mathcal{R} &= \{ \rho_1^{(1)}, \\ &\quad (\rho_1^{(2)}, \rho_2^{(2)}), \\ &\quad \vdots \\ &\quad (\rho_1^{(n-1)}, \dots, \rho_{n-1}^{(n-1)}), \\ &\quad (\lambda_1, \dots, \lambda_n) \}, \end{aligned}$$

and  $n-1$  positive real numbers  $\sigma_1, \dots, \sigma_{n-1}$ . If  $A$  is a matrix of order  $n$  and  $b$  a nonzero  $n$ -dimensional vector, then the following assertions are equivalent:

1. The Hessenberg matrix generated by the Arnoldi process applied to  $A$  and initial Arnoldi vector  $b$  has eigenvalues  $\lambda_1, \dots, \lambda_n$ , subdiagonal entries  $\sigma_1, \dots, \sigma_{n-1}$  and  $\rho_1^{(k)}, \dots, \rho_k^{(k)}$  are the eigenvalues of its  $k$ th leading principal submatrix for all  $k = 1, \dots, n-1$ .
2. The matrix  $A$  is of the form

$$A = V D_\sigma U(S)^{-1} C^{(n)} U(S) D_\sigma^{-1} V^*$$

and  $b = \|b\|Ve_1$ , where  $V$  is a unitary matrix,  $D_\sigma$  is the diagonal matrix

$$D_\sigma = \text{diag}(1, \sigma_1, \sigma_1\sigma_2, \dots, \prod_{j=1}^{n-1} \sigma_j),$$

$U(\mathcal{S})$  is the Ritz value companion transform in (2.2) and  $C^{(n)}$  is the companion matrix of the polynomial with roots  $\lambda_1, \dots, \lambda_n$ .

Corollary 2.3 is an analogue of Theorem 1.1 on arbitrary convergence of the GMRES method. Here we prescribe  $k$  values (the  $k$  Ritz values) in the  $k$ th iteration, whereas Theorem 1.1 prescribes one value (the  $k$ th residual norm); the spectrum of  $A$  is prescribed in both results. Note that in [42] it was shown that if the Arnoldi method produces a *particular* sequence of  $n(n+1)/2$  Ritz values, the same sequence can be generated by a whole class of matrices together with initial Arnoldi vectors. The paper also gives a description of this class. It can be seen as an analogue of the earlier result of Greenbaum and Strakoš [20], showing that if a residual norm convergence curve is generated by GMRES, the same curve can be obtained by a whole class of matrices together with right hand sides. Our corollary shows, surprisingly, that for general non-normal matrices the distribution of the Ritz values generated in the Arnoldi method can be arbitrary and fully independent on the spectrum. We remark that there exist some results on the distribution of Ritz values for specific non-normal matrices, for example for Jordan blocks and block diagonal matrices with a simple normal eigenvalue, see [7].

The given parametrization may give some additional insight in the convergence behavior of versions of Arnoldi used in practice, e.g. implicitly restarted Arnoldi with polynomial shifts [4, 5]; in particular it may help to better understand cases where Arnoldi with exact shifts fails, see, e.g. [11]. As Ritz values are contained in the field of values, it may also have implications for field of values-based analysis of iterative methods.

We here deal with the problem of constructing both an input matrix and an initial vector to produce prescribed Ritz values. In Corollary 2.3 the initial vector  $b = \|b\|Ve_1$  could be chosen arbitrarily if we define  $A$  appropriately, since the only requirement for the matrix  $V$  is to be unitary. When the matrix  $A$  is given, changing  $b$  will, of course, change the Ritz values. Constructing an initial vector to produce prescribed Ritz values was done for the Lanczos method in [40]. If a hermitian matrix has distinct eigenvalues, the paper shows how to construct a perverse initial vector such that the Ritz values in the one but last iteration are as far from the eigenvalues as allowed by the interlacing property (see [12] for a generalization to the normal case).

Another consequence of Corollary 2.3 is that the Ritz values in the Arnoldi method are in general independent of the subdiagonal elements  $h_{k+1,k}$  of the generated Hessenberg matrix. This is not that strange if one realizes that  $h_{k+1,k}$  is not an element of the matrix  $H_k$  used to extract the current Ritz values. But on the other hand the independency from  $h_{k+1,k}$  is still surprising in view of the fact that one is used to regard the residual norm

$$(2.5) \quad \|AV^{(k)}y - \rho^{(k)}V^{(k)}y\| = h_{k+1,k}|e_k^T y|$$

for an eigenpair  $(\rho^{(k)}, y)$  of  $H_k$ , see (2.1), as a measure for the quality of the approximate Ritz value-vector pair  $(\rho^{(k)}, V^{(k)}y)$ . Corollary 2.3 shows that, in theory, any small nonzero value of  $h_{k+1,k}$  is possible with  $\rho^{(k)}$  arbitrarily far from the eigenvalues of  $A$ . And conversely, all eigenvalues of  $H_k$  may coincide with eigenvalues of  $A$  with an arbitrarily large value of  $h_{k+1,k}$ . Though it is known that the residual norm is not always indicative for the quality of the Ritz values, see e.g. [8, 16], one might expect that in such counterintuitive cases, the misleading behavior of  $h_{k+1,k}$  is compensated by  $|e_k^T y|$  in (2.5). But consider the following: Let  $A$  be parameterized as  $A = VH(\mathcal{R})V^*$  and  $b = Ve_1$  and let for an approximate Ritz value-vector pair  $(\rho^{(k)}, V^{(k)}y)$  the residual norm in (2.5) be  $|e_k^T y|$  (all subdiagonal entries  $h_{k+1,k}$  of  $H(\mathcal{R})$  are one) where

$$H(\mathcal{R})_k y = \rho^{(k)} y.$$

For any choice of arbitrarily small nonzero entries  $\sigma_1, \dots, \sigma_{n-1}$ , the matrix  $VD_\sigma H(\mathcal{R})D_\sigma^{-1}V^*$  with  $D_\sigma = \text{diag}(1, \sigma_1, \dots, \prod_{j=1}^{n-1} \sigma_j)$  generates the same Ritz value  $\rho^{(k)}$ , but the residual norm in (2.5) will change as  $\sigma_k |e_k^T y_s|$  where

$$(D_{\sigma_k} H(\mathcal{R})_k D_{\sigma_k}^{-1}) y_s = \rho^{(k)} y_s$$

with  $D_{\sigma_k} = \text{diag}(1, \sigma_1, \dots, \prod_{j=1}^{k-1} \sigma_j)$ . However, the eigenvector  $y_s$  is nothing but a scaling of  $y$  because

$$(D_{\sigma_k} H(\mathcal{R})_k D_{\sigma_k}^{-1}) (D_{\sigma_k} y) = \rho^{(k)} (D_{\sigma_k} y),$$

i.e.  $y_s = D_{\sigma_k} y$ . This means that, with appropriate subdiagonal entries, the value  $|e_k^T y_s|$  can be small *too* (even if  $y_s$  is normalized) and does not compensate for a small  $\sigma_k$ , in spite of a possibly diverging Ritz value  $\rho^{(k)}$ . Something similar can be said about cases where all eigenvalues of  $H_k$  coincide with eigenvalues of  $A$  for arbitrarily large values of  $\sigma_k$ .

**3. Prescribed convergence behavior of the Arnoldi and the GMRES methods for the same pair  $\{A, b\}$ .** The diagonal matrix  $D_\sigma$  with positive entries in Corollary 2.3 contains the subdiagonal entries of the generated Hessenberg matrix and it can be chosen arbitrarily, for any prescribed Ritz values. Because the values of these subdiagonal entries influence the residual norms generated by the GMRES method applied to the corresponding linear system, there is a chance we can modify the behavior of GMRES while maintaining the prescribed Ritz values. This is what we will investigate next. Rather than directly choosing the diagonal matrix  $D_\sigma$  to control GMRES convergence, we will derive an alternative parametrization of the matrices and initial Arnoldi vectors that generate a given set of Ritz values. This parametrization will reveal the relation with the parametrization in Theorem 1.1 and thus might enable to combine prescribing Ritz values with prescribing GMRES residual norms.

The parametrization in Corollary 2.3 is based on a unitary matrix  $V$  whose columns span the  $n$ th Krylov subspace  $\mathcal{K}_n(A, b)$  whereas the parametrization in Theorem 1.1 works with a unitary matrix  $W$  whose columns span  $AK_n(A, b)$ . To better understand the relation between Corollary 2.3 and Theorem 1.1, we will translate the former parametrization in terms of the latter. To achieve this, we will use two factorizations of the Krylov matrix

$$K \equiv [b, Ab, A^2b, \dots, A^{n-1}b],$$

one with  $V$  and one with  $W$ . The first factorization is nothing but the QR decomposition

$$(3.1) \quad K = VU$$

of  $K$ . By *the* QR decomposition we will always mean the unique QR decomposition whose upper triangular factor has positive real main diagonal. The upper triangular factor  $U$  is related to the generated Ritz values as follows.

**LEMMA 3.1.** *Let  $H$  be the Hessenberg matrix generated by an Arnoldi process terminating at the  $n$ th iteration applied to  $A$  and  $b$  and let  $U(\mathcal{S})$  be the Ritz value companion transform in (2.2) corresponding to the generated strict Ritz values. Then the upper triangular factor  $U$  of the QR factorization (3.1) of the Krylov matrix  $K$  is*

$$U = \|b\| \text{diag}(1, h_{2,1}, h_{2,1}h_{3,2}, \dots, \prod_{j=1}^{n-1} h_{j+1,j}) U(\mathcal{S})^{-1}.$$

*Proof.* Any Arnoldi process (terminating at the  $n$ th iteration) can be written according to the parametrization of Corollary 2.3 with  $D_\sigma = \text{diag}(1, h_{2,1}, \dots, \prod_{j=1}^{n-1} h_{j+1,j})$ . Then in the Krylov matrix

$$K = [b, Ab, \dots, A^{n-1}b]$$

we can take  $\|b\|V$  out of the brackets to factor it since

$$\begin{aligned} b &= \|b\|V e_1 \\ Ab &= \|b\|V D_\sigma U(\mathcal{S})^{-1} C^{(n)} U(\mathcal{S}) D_\sigma^{-1} e_1 \\ A^2 b &= \|b\|V \left( D_\sigma U(\mathcal{S})^{-1} C^{(n)} U(\mathcal{S}) D_\sigma^{-1} \right)^2 e_1 \\ &\dots = \dots \\ A^{n-1} b &= \|b\|V \left( D_\sigma U(\mathcal{S})^{-1} C^{(n)} U(\mathcal{S}) D_\sigma^{-1} \right)^{n-1} e_1. \end{aligned}$$

Therefore

$$K = \|b\|V \left[ e_1, D_\sigma U(\mathcal{S})^{-1} C^{(n)} U(\mathcal{S}) D_\sigma^{-1} e_1, \dots, \left( D_\sigma U(\mathcal{S})^{-1} C^{(n)} U(\mathcal{S}) D_\sigma^{-1} \right)^{n-1} e_1 \right].$$

Now we would like to show that the last matrix on the right-hand side is just  $D_\sigma U(\mathcal{S})^{-1}$ . The first entry of the diagonal matrix  $D_\sigma$  being one we have  $U(\mathcal{S}) D_\sigma^{-1} e_1 = e_1$ . Obviously we have  $(D_\sigma U(\mathcal{S})^{-1} C^{(n)} U(\mathcal{S}) D_\sigma^{-1})^j = (D_\sigma U(\mathcal{S})^{-1} (C^{(n)})^j U(\mathcal{S}) D_\sigma^{-1})$ . Hence  $(D_\sigma U(\mathcal{S})^{-1} C^{(n)} U(\mathcal{S}) D_\sigma^{-1})^j e_1 = D_\sigma U(\mathcal{S})^{-1} (C^{(n)})^j e_1$ . It is straightforward to see that  $(C^{(n)})^j e_1 = e_{j+1}$ . This yields

$$\left( D_\sigma U(\mathcal{S})^{-1} C^{(n)} U(\mathcal{S}) D_\sigma^{-1} \right)^j e_1 = D_\sigma U(\mathcal{S})^{-1} e_{j+1}, \quad j = 0, \dots, n-1$$

and hence we have the factorization  $K = \|b\|V D_\sigma U(\mathcal{S})^{-1}$ . On the other hand  $K = VU$ . The uniqueness of the QR factorization gives  $U = \|b\|D_\sigma U(\mathcal{S})^{-1}$ .  $\square$

A similar result is proven in [26, Proposition 3.1]. The second factorization of  $K$  which we need involves the unitary factor  $W$ . We prove the following result in the same way as the previous lemma; it was also proved in [2] in a different way.

**LEMMA 3.2.** *Consider a matrix  $A$  with initial Arnoldi vector  $b$  such that the Arnoldi process does not terminate before iteration  $n$ . If we write  $A$  as  $A = WY C^{(n)} Y^{-1} W^*$  and  $b$  as  $b = Wh$  according to Theorem 1.1, then we have*

$$K = WY.$$

*Proof.* With Theorem 1.1 the Krylov matrix is defined as

$$K = [Wh, AWh, A^2Wh, \dots, A^{n-1}Wh].$$

We wish to take  $W$  out of the brackets to factor  $K$ . This can be done since

$$\begin{aligned} AW &= WY C^{(n)} Y^{-1} \\ A^2 W &= W(Y C^{(n)} Y^{-1})^2 \\ &\dots = \dots \\ A^{n-1} W &= W(Y C^{(n)} Y^{-1})^{n-1}. \end{aligned}$$

Therefore

$$K = W \left[ h, YC^{(n)}Y^{-1}h, \dots, (YC^{(n)}Y^{-1})^{n-1}h \right].$$

Now we would like to show that the last matrix on the right-hand side is just  $Y$ . The vector  $h$  being the first column of  $Y$  we have  $h = Ye_1$ . Obviously we have  $(YC^{(n)}Y^{-1})^j = Y(C^{(n)})^jY^{-1}$ . Hence  $(YC^{(n)}Y^{-1})^j h = Y(C^{(n)})^j e_1$ . As before,  $(C^{(n)})^j e_1 = e_{j+1}$ . This yields

$$(YC^{(n)}Y^{-1})^j h = Ye_{j+1}, \quad j = 0, \dots, n-1$$

and this proves the result.  $\square$

With the two factorizations  $K = VU = WY$  we are ready for a second parametrization, formulated with the notation of Theorem 1.1 and based on the unitary matrix  $W$ , of the pairs  $\{A, b\}$  generating arbitrary Ritz values.

**THEOREM 3.3.** *Assume we are given a set of tuples of complex numbers*

$$\begin{aligned} \mathcal{R} = & \{ \rho_1^{(1)}, \\ & (\rho_1^{(2)}, \rho_2^{(2)}), \\ & \vdots \\ & (\rho_1^{(n-1)}, \dots, \rho_{n-1}^{(n-1)}), \\ & (\lambda_1, \dots, \lambda_n) \}, \end{aligned}$$

such that  $(\lambda_1, \dots, \lambda_n)$  contains only nonzero numbers, and  $n-1$  positive real numbers  $\sigma_1, \dots, \sigma_{n-1}$ . If  $A$  is a matrix of order  $n$  and  $b$  a nonzero  $n$ -dimensional vector, then the following assertions are equivalent:

1. The Hessenberg matrix generated by the Arnoldi process applied to  $A$  and initial Arnoldi vector  $b$  has eigenvalues  $\lambda_1, \dots, \lambda_n$ , subdiagonal entries  $\sigma_1, \dots, \sigma_{n-1}$  and  $\rho_1^{(k)}, \dots, \rho_k^{(k)}$  are the eigenvalues of its  $k$ th leading principal submatrix for all  $k = 1, \dots, n-1$ .
2. The matrix  $A$  is of the form

$$A = WYC^{(n)}Y^{-1}W^*$$

and  $b = Wh$ , where  $W$  is a unitary matrix,  $C^{(n)}$  is the companion matrix corresponding to the eigenvalues  $\lambda_1, \dots, \lambda_n$  and  $Y$  is of the form

$$Y = \begin{bmatrix} h & R \\ & 0 \end{bmatrix}.$$

$R$  is the upper triangular matrix

$$(3.2) \quad R = \Gamma L^* T,$$

of order  $n-1$ , where  $T$  is the trailing principal submatrix in the partitioning

$$(3.3) \quad \|b\| \operatorname{diag}(1, \sigma_1, \sigma_1 \sigma_2, \dots, \prod_{j=1}^{n-1} \sigma_j) U(\mathcal{S})^{-1} = \begin{bmatrix} \|b\| & t^* \\ 0 & T \end{bmatrix},$$

of the scaled inverse of the Ritz value companion transform  $U(\mathcal{S})$  in (2.2) and  $L$  is the lower triangular factor in the Cholesky decomposition

$$(3.4) \quad LL^* = I_{n-1} + T^{-*} t t^* T^{-1}.$$

The diagonal matrix  $\Gamma$  with unit modulus entries is such that

$$(3.5) \quad e_k^T \Gamma L^{-1} T^{-*} t \geq 0, \quad k = 1, \dots, n-1$$

and the entries of  $h = [\eta_1, \dots, \eta_n]^T$  satisfy

$$(3.6) \quad [\eta_1, \dots, \eta_{n-1}]^T = \|b\| \Gamma L^{-1} T^{-*} t, \quad \eta_n = \|b\| \sqrt{1 - \|L^{-1} T^{-*} t\|^2}.$$

*Proof.* First we prove the implication  $1 \rightarrow 2$ . Because the Arnoldi process does not stop before the last iteration, GMRES applied to the linear system with matrix  $A$ , right-hand side  $b$  and zero initial guess does not stop before the last iteration, and we can write  $A = WY C^{(n)} Y^{-1} W^*$  and  $b = Wh$  according to Theorem 1.1. From Lemma 3.2, the factorization (3.1) and Lemma 3.1 we have

$$K^* K = Y^* W^* W Y = Y^* Y, \quad K^* K = U^* V^* V U = \|b\|^2 U(S)^{-*} D_\sigma^T D_\sigma U(S)^{-1}.$$

Hence the matrix  $Y$  from the parametrization must satisfy

$$Y^* Y = \|b\|^2 U(S)^{-*} D_\sigma^T D_\sigma U(S)^{-1}.$$

Let  $\hat{h} = [\eta_1, \dots, \eta_{n-1}]^T$  be the vector of the first  $n-1$  components of  $h$  from (1.2). Then from (1.1) we have

$$(3.7) \quad Y^* Y = \begin{bmatrix} \|h\|^2 & \hat{h}^* R \\ R^* \hat{h} & R^* R \end{bmatrix}.$$

Comparing (3.7) with  $\|b\|^2 U(S)^{-*} D_\sigma^T D_\sigma U(S)^{-1}$  and using the partitioning (3.3), we obtain for  $R$  and  $\hat{h}$  the conditions

$$(3.8) \quad R^* R = T^* T + t t^*, \quad \hat{h} = \|b\| R^{-*} t.$$

Furthermore, we have the conditions  $\eta_k \geq 0$ ,  $k = 1, \dots, n-1$ , because all entries of  $\hat{h}$  correspond to entries describing the GMRES convergence curve according to (1.2).

Let  $L$  be the lower triangular factor in the Cholesky decomposition

$$L L^* = I_{n-1} + T^{-*} t t^* T^{-1},$$

let  $\Gamma$  be a diagonal matrix with unit modulus entries and let  $R = \Gamma L^* T$ . Then

$$R^* R = T^* L \Gamma^* \Gamma L^* T = T^* (I_{n-1} + T^{-*} t t^* T^{-1}) T = T^* T + t t^*$$

is always satisfied and  $\Gamma$  can be chosen such that

$$e_k^T \Gamma L^{-1} T^{-*} t \geq 0, \quad k = 1, \dots, n-1.$$

It follows that

$$\hat{h} = \|b\| R^{-*} t = \|b\| \Gamma L^{-1} T^{-*} t$$

and with  $\|h\| = \|W^* b\| = \|b\|$  we obtain

$$\eta_n = \sqrt{\|h\|^2 - \|\hat{h}\|^2} = \|b\| \sqrt{1 - \|L^{-1} T^{-*} t\|^2}.$$

For the implication  $2 \rightarrow 1$ , let  $A = WYC^{(n)}Y^{-1}W^*$  be the parametrization of  $A$  given in assertion 2 and let  $b = Wh$ . By Lemma 3.2,  $K = WY$  and let  $K = V\tilde{U}$  be the QR factorization of the Krylov matrix  $K$ . We first show that  $\tilde{U} = \|b\|D_\sigma U(\mathcal{S})^{-1}$ .

In the QR decomposition  $K = V\tilde{U}$  we have  $Ve_1 = b/\|b\|$  and therefore we can partition  $\tilde{U}$  as

$$(3.9) \quad \tilde{U} = \begin{bmatrix} \|b\| & \tilde{t}^* \\ 0 & \tilde{T} \end{bmatrix}.$$

With the first part of the proof

$$R^*R = \tilde{T}^*\tilde{T} + \tilde{t}\tilde{t}^*, \quad \hat{h} = \|b\|R^{-*}\tilde{t},$$

see (3.8), i.e.

$$\tilde{t} = \frac{R^*\hat{h}}{\|b\|}, \quad \tilde{T}^*\tilde{T} = R^*R - \frac{R^*\hat{h}\hat{h}^*R}{\|b\|^2}.$$

But by assumption, we have for  $t$  and  $T$  from (3.4) and (3.6) the same equalities,

$$t = \frac{T^*L\Gamma^*\hat{h}}{\|b\|} = \frac{R^*\hat{h}}{\|b\|},$$

$$T^*T = T^*(LL^* - T^{-*}tt^*T^{-1})T = T^*L\Gamma^*\Gamma L^*T - tt^* = R^*R - \frac{R^*\hat{h}\hat{h}^*R}{\|b\|^2}.$$

The matrix  $R^*R - \frac{R^*\hat{h}\hat{h}^*R}{\|b\|^2}$  is positive definite since it is the Schur complement of  $\|h\|^2$  in  $Y^*Y$ , which is positive definite. Therefore the Cholesky decomposition of the matrix  $R^*R - \frac{R^*\hat{h}\hat{h}^*R}{\|b\|^2}$  exists and  $\tilde{T} = T$  is the unique Cholesky factor. Together with  $\tilde{t} = t = \frac{R^*\hat{h}}{\|b\|}$  we have

$$\tilde{U} = \|b\|D_\sigma U(\mathcal{S})^{-1}.$$

Because of  $K = WY = V\tilde{U}$  and with (2.3) it follows that

$$\begin{aligned} A &= WYC^{(n)}Y^{-1}W^* = V\tilde{U}C^{(n)}\tilde{U}^{-1}V^* \\ &= VD_\sigma U(\mathcal{S})^{-1}C^{(n)}U(\mathcal{S})D_\sigma^{-1}V^* = VD_\sigma H(\mathcal{R})D_\sigma^{-1}V^*. \end{aligned}$$

The upper Hessenberg matrix  $D_\sigma H(\mathcal{R})D_\sigma^{-1}$  generated by the Arnoldi method therefore has the prescribed Ritz values and subdiagonal entries.  $\square$

Note that Theorem 3.3 and Corollary 2.3 are not fully equivalent. In Theorem 3.3 we must assume, for reasons of compatibility with Theorem 1.1, that the spectrum of  $A$  does not contain the origin. In Corollary 2.3 the only free parameters are a unitary matrix and the norm of the initial Arnoldi vector. In Theorem 3.3 there appears to be slightly more freedom because a unit modulus entry of  $\Gamma$  can lie anywhere on the unit circle if the corresponding entry of  $L^{-1}T^{-*}t$  is zero, see (3.5). There is of course much less freedom in Theorem 3.3 than there is in the parametrization of Theorem 1.1 when prescribing a GMRES convergence curve.

We see that by modifying the choice of the subdiagonal entries  $\sigma_1, \dots, \sigma_{n-1}$  in Theorem 3.3, we might modify the vector  $h$  representing the GMRES convergence curve generated with  $A$  and  $b$  while maintaining the prescribed Ritz values, i.e. while leaving the Ritz value companion transform  $U(\mathcal{S})$  in (3.3) unchanged. Does this mean we can force any GMRES convergence speed with arbitrary Ritz values? There is one situation where this is certainly not possible: When there is a zero Ritz value in some iteration, this implies a singular Hessenberg matrix and corresponds

to an indefinable iterate in the FOM method, which is equivalent to stagnation in the parallel GMRES process, see e.g. [6, 17]. Hence zero Ritz values are equivalent with GMRES stagnation. For completeness, we give another proof of this well-known fact, formulated with the notation of Theorem 3.3.

LEMMA 3.4. *With the notation of Theorem 3.3 and for  $1 \leq k \leq n-1$ , the  $k$ -tuple  $(\rho_1^{(k)}, \dots, \rho_k^{(k)})$  contains a zero Ritz value if and only if  $\eta_k = 0$  in (3.6).*

*Proof.* Denote by  $U(\mathcal{S})$  the Ritz value companion transform in (2.2) and let it be partitioned according to (3.3) as

$$U(\mathcal{S}) = \|b\| D_\sigma \begin{bmatrix} \|b\| & t^* \\ 0 & T \end{bmatrix}^{-1} = \|b\| D_\sigma \begin{bmatrix} \frac{1}{\|b\|} & \frac{-t^* T^{-1}}{\|b\|} \\ 0 & T^{-1} \end{bmatrix},$$

where  $D_\sigma = \text{diag}(1, \sigma_1, \sigma_1 \sigma_2, \dots, \prod_{j=1}^{n-1} \sigma_j)$ . By definition of  $U(\mathcal{S})$ , the  $k$ -tuple  $(\rho_1^{(k)}, \dots, \rho_k^{(k)})$  contains a zero Ritz value if and only if  $t^* T^{-1} e_k = 0$ . It can easily be checked that the lower triangular factor  $L$  in the Cholesky decomposition

$$LL^* = I_{n-1} + T^{-*} t t^* T^{-1}$$

has its  $k$ th row and column zero, except for the diagonal entry, if and only if  $t^* T^{-1} e_k = 0$ . Then the vector  $\hat{h}$ , being the solution of the lower triangular system

$$L \Gamma^* \hat{h} = T^{-*} t$$

has  $k$ th entry zero if and only if  $t^* T^{-1} e_k = 0$ .  $\square$

Thus GMRES residual norms cannot be fully independent of Ritz values. However, we will show that the *only* restriction Ritz values put on GMRES residual norms is precisely that zero Ritz values imply stagnation. Otherwise, any GMRES behavior is possible with arbitrary prescribed Ritz values. Before proving this, we need the following auxiliary result.

LEMMA 3.5. *Consider  $n$  positive real numbers*

$$f(0) \geq f(1) \geq \dots \geq f(n-1) > 0$$

*and define*

$$\eta_k = (f(k-1)^2 - f(k)^2)^{1/2}, \quad k < n, \quad \eta_n = f(n-1), \quad \hat{h} = [\eta_1, \dots, \eta_{n-1}]^T.$$

*If we denote by  $R_h$  the upper triangular factor of the Cholesky decomposition*

$$R_h^T R_h = I_{n-1} - \frac{\hat{h} \hat{h}^T}{f(0)^2},$$

*then we have*

$$e_k^T R_h^{-T} \hat{h} = 0 \quad \Leftrightarrow \quad f(k-1) = f(k), \quad k = 1, \dots, n-1.$$

*Proof.* The entries of  $R_h^T$  are

$$(3.10) \quad (R_h^T)_{i,k} = \frac{-\eta_i \eta_k}{\sqrt{\eta_{k+1}^2 + \dots + \eta_n^2} \sqrt{\eta_k^2 + \dots + \eta_n^2}}, \quad (R_h^T)_{k,k} = \frac{\sqrt{\eta_{k+1}^2 + \dots + \eta_n^2}}{\sqrt{\eta_k^2 + \dots + \eta_n^2}},$$

see [15] on the Cholesky decomposition of a rank-one updated identity matrix, or also [27, Theorem 4.2]. Therefore, if  $\eta_k = 0$  for some  $k \leq n - 1$ , then the  $k$ th row and  $k$ th column of  $R_h^T$  are zero except for the main diagonal entry. It is easily seen from solving the lower triangular system  $R_h^T x = \hat{h}$  with forward substitution that  $x = R_h^{-T} \hat{h}$  is zero only there where  $\hat{h}$  is zero.  $\square$

THEOREM 3.6. *Consider a set of tuples of complex numbers*

$$\mathcal{R} = \{ \rho_1^{(1)}, \\ (\rho_1^{(2)}, \rho_2^{(2)}), \\ \vdots \\ (\rho_1^{(n-1)}, \dots, \rho_{n-1}^{(n-1)}), \\ (\lambda_1, \dots, \lambda_n) \},$$

such that  $(\lambda_1, \dots, \lambda_n)$  contains no zero number, and  $n$  positive numbers

$$f(0) \geq f(1) \geq \dots \geq f(n-1) > 0,$$

such that  $f(k-1) = f(k)$  if and only if the  $k$ -tuple  $(\rho_1^{(k)}, \dots, \rho_k^{(k)})$  contains a zero number. Let  $A$  be a square matrix of size  $n$  and let  $b$  be a nonzero  $n$ -dimensional vector. The following assertions are equivalent:

1. The GMRES method applied to  $A$  and right-hand side  $b$  with zero initial guess yields residuals  $r^{(k)}$ ,  $k = 0, \dots, n-1$  such that

$$\|r^{(k)}\| = f(k), \quad k = 0, \dots, n-1,$$

$A$  has eigenvalues  $\lambda_1, \dots, \lambda_n$ , and  $\rho_1^{(k)}, \dots, \rho_k^{(k)}$  are the eigenvalues of the  $k$ th leading principal submatrix of the generated Hessenberg matrix for all  $k = 1, \dots, n-1$ .

2. The matrix  $A$  is of the form

$$A = WY C^{(n)} Y^{-1} W^*$$

and  $b = Wh$ , where  $W$  is a unitary matrix and  $C^{(n)}$  is the companion matrix corresponding to the polynomial with roots  $\lambda_1, \dots, \lambda_n$ .  $Y$  is given by

$$Y = \begin{bmatrix} h & R \\ & 0 \end{bmatrix},$$

$h$  being the vector

$$h = [\eta_1, \dots, \eta_n]^T, \quad \eta_k = (f(k-1)^2 - f(k)^2)^{1/2}, \quad k < n, \quad \eta_n = f(n-1),$$

and  $R$  being the nonsingular upper triangular matrix of order  $n-1$

$$(3.11) \quad R = R_h^{-1} D_c^{-*} C^{-1},$$

where  $C$  is the trailing principal submatrix in the partitioning

$$(3.12) \quad U(\mathcal{S}) = \begin{bmatrix} 1 & c^* \\ 0 & C \end{bmatrix}$$

of the Ritz value companion transform  $U(\mathcal{S})$  for  $\mathcal{R}$  defined in (2.2).  $R_h$  is the upper triangular factor of the Cholesky decomposition

$$R_h^T R_h = I_{n-1} - \frac{\hat{h}\hat{h}^T}{f(0)^2},$$

for  $\hat{h} = [\eta_1, \dots, \eta_{n-1}]^T$  and  $D_c$  is a nonsingular diagonal matrix such that

$$(3.13) \quad R_h^{-T} \hat{h} = -f(0)^2 D_c c.$$

*Proof.* Because of Theorem 1.1 it is clear that the parametrization given here generates the prescribed GMRES residual norms and vice-versa. Hence it suffices to show the given parametrization generates the prescribed Ritz values and vice-versa. For this we will use the parametrization of Theorem 3.3 and prove that the matrix  $R$  in (3.11) satisfies the same conditions as the upper triangular  $R$  in (3.2) in Theorem 3.3.

First we show that the nonsingular diagonal matrix  $D_c$  used to define  $R$  in (3.11) exists. With the assumed partitioning (3.12) of  $U(\mathcal{S})$  and by the definition of  $U(\mathcal{S})$ , the entries of  $c$  are zero precisely at positions corresponding to iterations with a zero Ritz value. By assumption,  $\hat{h}$  is zero at exactly these positions and so is  $R_h^{-T} \hat{h}$  with Lemma 3.5. Thus we can always define a nonsingular diagonal matrix  $D_c$  such that

$$R_h^{-T} \hat{h} = -f(0)^2 D_c c.$$

Now with the definition (3.11) of  $R$  we have

$$R^* \hat{h} = -f(0)^2 C^{-*} c.$$

Next, in analogy with (3.3), consider the partitioning

$$(3.14) \quad \text{diag}(f(0), D_c^{-*}) U(\mathcal{S})^{-1} = \begin{bmatrix} f(0) & t^* \\ 0 & T \end{bmatrix},$$

of a diagonal scaling of  $U(\mathcal{S})^{-1} = \begin{bmatrix} 1 & -c^* C^{-1} \\ 0 & C^{-1} \end{bmatrix}$ . It follows that

$$t = -f(0) C^{-*} c = \frac{R^* \hat{h}}{f(0)}$$

and

$$T = D_c^{-*} C^{-1}.$$

To prove that the matrix  $R$  in (3.11) satisfies the same conditions as the upper triangular  $R$  in (3.2) in Theorem 3.3, it remains to show that  $R_h^{-1} = L^*$ ,  $\Gamma = I_{n-1}$ , where  $L$  and  $\Gamma$  are the matrices defined in the second assertion of Theorem 3.3. We have

$$\begin{aligned} I_{n-1} + T^{-*} t t^* T^{-1} &= I_{n-1} + D_c C^* \frac{R^* \hat{h}}{f(0)} \left( D_c C^* \frac{R^* \hat{h}}{f(0)} \right)^* \\ &= I_{n-1} + \frac{R_h^{-T} \hat{h}}{f(0)} \left( \frac{R_h^{-T} \hat{h}}{f(0)} \right)^* = R_h^{-T} \left( R_h^T R_h + \frac{\hat{h}\hat{h}^*}{f(0)^2} \right) R_h^{-1} = R_h^{-T} R_h^{-1} \end{aligned}$$

and with  $\Gamma = I_{n-1}$

$$e_k^T R_h^T T^{-*} t = e_k^T R_h^T \frac{R_h^{-T} \hat{h}}{f(0)} = \frac{\eta_k}{f(0)} \geq 0, \quad k = 1, \dots, n-1.$$

Together with

$$\eta_n = f(n-1) = \sqrt{f(0)^2 - (f(0)^2 - f(1)^2) - \dots - (f(n-2)^2 - f(n-1)^2)} = f(0) \sqrt{1 - \frac{\|\hat{h}\|^2}{f(0)^2}},$$

we have that matrices of the form

$$W \begin{bmatrix} h & R \\ & 0 \end{bmatrix} C(\mathcal{R}^{(n)}) \begin{bmatrix} h & R \\ & 0 \end{bmatrix}^{-1} W^*$$

and right-hand sides  $Wh$  generate the prescribed Ritz values and vice-versa, see Theorem 3.3.  $\square$

The only freedom we have to prescribe both Ritz values and GMRES residual norms is in the unitary matrix  $W$  and in those entries of the diagonal matrix  $D_c$  on positions corresponding to iterations with a zero Ritz value or, equivalently, on positions corresponding to iterations where GMRES stagnates. On these positions  $D_c$  may have arbitrary values. In this sense we have exhausted all the degrees of freedom; GMRES and Arnoldi are invariant under unitary transformation and more values than Ritz values and residual norms cannot be prescribed for the same Arnoldi process.

Theorem 3.6 says that one can construct matrices and right-hand sides for which converged Ritz values need not imply accelerated convergence speed in the GMRES method, as is the case for the CG method for hermitian positive definite matrices [44]. The only restriction Ritz values put on GMRES is that a zero Ritz value leads to stagnation in the corresponding iteration. A restricted role of Ritz values for GMRES may be expected in view of the fact that the Ritz values are *not* the roots of the polynomials GMRES generates to compute its residuals. These roots are the harmonic Ritz values [34, 17]. Although harmonic Ritz values generated in the Arnoldi procedure might be prescribed in a similar way as we did for ordinary Ritz values in the previous section [28], it is not clear whether this is possible with given GMRES residual norms. Nonetheless, the extent to which ordinary Ritz values and residual norms are independent is astonishing. Note, for example, that for matrices close to normal the bounds derived in [45] suggest that as soon as eigenvalues of such matrices are sufficiently well approximated by Ritz values, GMRES from then on converges at least as fast as for a related system in which these eigenvalues are missing. This may be surprising but it is not contradictory.

Note that we could also have formulated the second assertion in the previous theorem analogously to the second assertion in Theorem 3.3. Then the diagonal scaling matrix in (3.3) takes the form of the diagonal matrix in (3.14); otherwise the assertion needs not be changed. Translated in the notation of Corollary 2.3, this gives the following alternative parametrization.

**COROLLARY 3.7.** *Assume we are given a set of tuples of complex numbers*

$$\begin{aligned} \mathcal{R} = & \{ \rho_1^{(1)}, \\ & (\rho_1^{(2)}, \rho_2^{(2)}), \\ & \vdots \\ & (\rho_1^{(n-1)}, \dots, \rho_{n-1}^{(n-1)}), \\ & (\lambda_1, \dots, \lambda_n) \}, \end{aligned}$$

such that  $(\lambda_1, \dots, \lambda_n)$  contains no zero number, and  $n$  positive real numbers

$$f(0) \geq f(1) \geq \dots \geq f(n-1) > 0,$$

such that  $f(k-1) = f(k)$  if and only if the  $k$ -tuple  $(\rho_1^{(k)}, \dots, \rho_k^{(k)})$  contains a zero number. If  $A$  is a matrix of order  $n$  and  $b$  a nonzero  $n$ -dimensional vector, then the following assertions are equivalent:

1. The GMRES method applied to  $A$  and right-hand side  $b$  with zero initial guess yields residuals  $r^{(k)}$ ,  $k = 0, \dots, n-1$  such that

$$\|r^{(k)}\| = f(k), \quad k = 0, \dots, n-1,$$

$A$  has eigenvalues  $\lambda_1, \dots, \lambda_n$ , and  $\rho_1^{(k)}, \dots, \rho_k^{(k)}$  are the eigenvalues of the  $k$ th leading principal submatrix of the generated Hessenberg matrix for all  $k = 1, \dots, n-1$ .

2. The matrix  $A$  is of the form

$$A = V \text{diag}(f(0), D_c^{-*}) U(\mathcal{S})^{-1} C^{(n)} U(\mathcal{S}) \text{diag}(f(0)^{-1}, D_c^*) V^*$$

and  $b = \|b\| V e_1$ , where  $V$  is a unitary matrix,  $U(\mathcal{S})$  is the Ritz value companion transform for  $\mathcal{R}$  defined in (2.2) and  $C^{(n)}$  is the companion matrix of the polynomial with roots  $\lambda_1, \dots, \lambda_n$ .  $D_c$  is a nonsingular diagonal matrix such that

$$R_h^{-T} \hat{h} = -f(0)^2 D_c c$$

with  $\hat{h}$  being the vector

$$\hat{h} = [\eta_1, \dots, \eta_{n-1}]^T, \quad \eta_k = (f(k-1)^2 - f(k)^2)^{1/2},$$

$R_h$  being the upper triangular factor of the Cholesky decomposition

$$R_h^T R_h = I_{n-1} - \frac{\hat{h} \hat{h}^T}{f(0)^2},$$

and  $c$  being the first row of  $U(\mathcal{S})$  without its diagonal entry.

This parametrization is based on unitary matrices  $V$  spanning  $\mathcal{K}_n(A, b)$  instead of unitary matrices  $W$  spanning  $A\mathcal{K}_n(A, b)$  and is therefore closer to the actual Arnoldi process which is run in standard implementations of the GMRES and Arnoldi methods. On the other hand, the parametrization in Theorem 3.6 reveals more clearly the relation with the prescribed residual norms. Note that we can easily change Corollary 3.7 to yield a “ $V$ -based” analogue of Theorem 1.1; it suffices to consider  $U(\mathcal{S})$  as a free parameter matrix. Corollary 3.7 also shows how to define the subdiagonal entries  $h_{k+1,k}$  of a Hessenberg matrix with prescribed Ritz values in order to obtain prescribed GMRES residual norms: They follow from the equality

$$f(0) \text{diag}(1, h_{2,1}, h_{2,1}h_{3,2}, \dots, \prod_{j=1}^{n-1} h_{j+1,j}) = \text{diag}(f(0), D_c^{-*}).$$

**4. Conclusions and future work.** The Arnoldi orthogonalization process is a cornerstone of several successful Krylov subspace methods for non-hermitian matrices. Nevertheless, two of the most popular methods based on it, the GMRES and the Arnoldi methods, can exhibit counterintuitive convergence behavior. For GMRES it is known for some time that any non-increasing convergence curve is possible and can be generated with any spectrum [19]; the fact that *all* Ritz values formed by the Arnoldi method can be prescribed appears not to have been noticed so far. The present paper also shows that arbitrary convergence of GMRES is possible not only with any spectrum, but even with any Ritz values for all iterations (provided we treat the stagnation case correctly).

Seen the success of (modified versions of) the GMRES and Arnoldi methods for a large variety of problems, the situations described in our theoretical results may occur rarely in solving practical problems in scientific computing. For example in the Arnoldi method, cases of Ritz values diverging further away from the spectrum in every iteration are possible as we proved in Section 2, but they happen for particular matrices only in combination with particular initial Arnoldi vectors. As one normally chooses the initial Arnoldi vector randomly, the chances that this vector produces diverging Ritz values may be small and in practice one can easily rerun the process with a different random initial Arnoldi vector. In the GMRES method, however, one is stuck to a given right-hand side and applications exist where the pathological cases described in [19] occur. An example is given by convection-diffusion problems, see e.g. [36] or [24, Fig. 3.10 and 3.11]. This type of problems also contains an illustration of our results of Section 3: In the convection dominated case, system matrices are often close to transposed Jordan blocks (i.e. upper Hessenberg matrices with identical Ritz values for all iterations) and, for certain boundary conditions, right-hand sides are close to the first unit vector [24]. Hence we have almost converged Ritz values from the very start, but this does not mean that GMRES converges rapidly as one would expect. On the contrary, it is known that these problems give very slow, nearly stagnating GMRES residual norms during the initial phase of convergence [13, 24].

It is often assumed that counterintuitive GMRES behavior, i.e. spectral information which is misleading for residual norms, is possible in the highly non-normal case only, and one may expect the counterintuitive results of this paper to be restricted to the highly non-normal case, too. None of the two statements is entirely correct; for instance arbitrary GMRES convergence curves are possible for such nice normal matrices as are the perfectly conditioned unitary matrices, see [20, Section 3.1] and [19]. As for our results on the Arnoldi method, certainly prescribed Ritz values outside the convex hull of the eigenvalues are possible with non-normal matrices only and probably the further one prescribes Ritz values away from the convex hull, the more non-normal the constructed input matrix must be. On the other hand, divergence *inside* the convex hull might still be possible with some normal but nonhermitian matrices. Very few appears to the authors to be known on this topic (for general normal matrices of size three, see e.g. [7]). Although there are generalized interlacing properties for normal matrices, they cannot be exploited because the leading principal submatrices of normal Hessenberg matrices need not be normal. Let us also recall that the Ritz values generated in the Lanczos method in the one but last iteration can be as far from the eigenvalues as allowed by the interlacing property [40].

Our results are of a theoretical nature and may give additional insight in the properties of the GMRES and the Arnoldi methods. An important issue related to our results is how to detect, a priori, whether a matrix with initial vector will lead to diverging Ritz value behavior in Arnoldi or to stagnation in GMRES. For GMRES, work on complete or partial stagnation was done for example in [47] or, recently, in [27], where the results are linked with the parametrization in Theorem 1.1. More generally, the question is whether our theory gives some insight on what is a good Arnoldi starting vector, respectively, right-hand side  $b$ . Work for the near future includes modifications of our results for popular restarted versions of Arnoldi or GMRES which may enhance

theoretical insight in the behavior of strategies that are frequently used in practice.

**Software.** At the link [http://www.cs.cas.cz/duintjertebbens/duintjertebbens\\_soft.html](http://www.cs.cas.cz/duintjertebbens/duintjertebbens_soft.html) the reader can find MATLAB subroutines to create matrices and initial vectors with the parametrizations in this paper.

**Acknowledgements.** The authors are indebted to Zdeněk Strakoš for initiating their work on this topic. They thank the anonymous referees for their comments and thank Russel Carden for pointing out reference [42].
