Preface

The aim of this handbook is to present most commonly used stochastic models for repairable systems and to consider some fundamental problems of estimating unknown parameters of these models. Special attention is paid to the trend-renewal process (TRP), which is recently widely discussed in the literature. The class of these processes covers non-homogeneous Poisson and renewal processes. As alternatives to the maximum likelihood (ML) method, three other methods of estimation are proposed for the models considered. The alternative methods, called the least squares (LS) method, the constrained least squares (CLS) method and the method of moments (M method) can be useful when the ML method fails (as for some non-homogeneous Poisson software reliability models) or the renewal distribution of a TRP is unknown.

In Chapter 1 some basic notions from survival analysis are reminded and the classification of lifetime distributions in terms of ageing is presented (IFR, DFR, IFRA, DFRA, NBU, NWU and bathtub-shaped failure classes). Chapter 2 provides a review of parametric families of lifetime distributions.

The most commonly used stochastic models for repairable systems, such as the homogeneous Poisson, renewal, non-homogeneous Poisson (with its special cases, with power law intensity function and with bounded mean value function) and TRP’s are described in Chapter 3. In the handbook a greater deal of attention is paid to the TRP’s, whose basic properties are presented in Sections 3.2.6 and 3.2.7. Maximum likelihood estimation problem in the non-homogeneous Poisson process with power law intensity function is considered in Chapter 4.

Chapter 5 is devoted to estimation problems in TRP models. In Section 5.2 the form of likelihood function for a TRP process is presented. The likelihood function and the likelihood equations for estimating the parameters of the TRP with Weibull renewal distribution and power law trend function are given in Section 5.3. Mainly, in Chapter 5, methods of estimating unknown parameters of a trend function for TRP’s are investigated in the case when the renewal distribu-
tion function of this process is unknown. If the renewal distribution is unknown, then the likelihood function of the TRP is unknown and consequently the ML method cannot be used. In such situation, in Section 5.4 three other methods of estimating the trend parameters are presented: the LS, CLS and M methods. The problem of estimating trend parameters of a TRP with unknown renewal distribution may be of interest in the situation when we observe several systems, of the same kind, working in different environments and we are interested in examining and comparing their trend functions, whatsoever their renewal distribution is. The estimation problem of the trend parameters in some special case of the TRP is considered in Section 5.5. In Section 5.6 the estimators proposed are examined and compared with the ML estimators (obtained under the additional assumption that the renewal distribution has a known parametric form) through a computer simulation study. Some real data are examined in Section 5.6.3. Section 5.7 contains conclusions and some prospects. Chapter 5 contains the results of Jokiel-Rokita and Magiera (2011).

In Chapter 6 a subclass of non-homogeneous Poisson processes is considered. This subclass with bounded mean value function can be used to model software reliability. The ML estimators of intensity parameters for a software reliability model are given in Section 6.2. In certain cases the ML estimators do not exist. In such cases the alternative methods of estimating proposed in Section 5.4 can be used. In Sections 6.3 and 6.5 the LS and CLS methods are applied to the software reliability model considered and to its special case. In Section 6.6 some numerical results illustrating the accuracy of the proposed LS and CLS estimators with comparison to the ML estimators are presented for a special case of the Erlangian non-homogeneous Poisson process software reliability model. Chapter 6 contains the results of Jokiel-Rokita and Magiera (2010).

## Preface

### 1 Classes of Lifetime Distributions in Reliability Models

1.1 Functions characterizing lifetime distributions .......................... 1
   1.1.1 Survival function .............................................. 1
   1.1.2 Failure rate function ........................................ 1
   1.1.3 Mean residual life function ................................. 3

1.2 Classification of lifetime distributions in terms of ageing .............. 4
   1.2.1 Increasing and decreasing failure rate classes ................. 4
   1.2.2 New better than used and new worse than used classes ....... 6
   1.2.3 Bathtub-shaped failure rate functions ....................... 7

## 2 Parametric Families of Lifetime Distributions

2.1 Gamma family ...................................................... 13
   2.1.1 Exponential distribution .................................... 13
   2.1.2 Negative exponential distribution .......................... 14
   2.1.3 Erlang distribution ........................................ 15
   2.1.4 Rayleigh distribution ...................................... 16
   2.1.5 Weibull distribution ....................................... 17
   2.1.6 Three-parameter Weibull distribution ...................... 19
   2.1.7 Gamma distribution ......................................... 19
   2.1.8 Three-parameter gamma distribution ....................... 20
   2.1.9 Four-parameter generalized gamma distribution ........... 20

2.2 Inverse gamma distribution ........................................ 20

2.3 Gompertz distribution ............................................. 21

2.4 Gumbel distributions ............................................. 21
   2.4.1 Double exponential distribution ............................. 21
   2.4.2 Generalized Gumbel distribution ............................ 23
   2.4.3 Extreme value distribution ................................. 23
2.4.4 Generalized extreme value distribution . . . . . . . . . . . . 24
2.5 Lognormal distributions . . . . . . . . . . . . . . . . . . . . . . . 25
2.6 Pareto family . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 26
  2.6.1 Pareto distribution . . . . . . . . . . . . . . . . . . . . . . . 26
  2.6.2 Generalized Pareto distribution . . . . . . . . . . . . . . . . 27
2.7 Burr distributions . . . . . . . . . . . . . . . . . . . . . . . . . . . 28
2.8 Time-transformed exponential family . . . . . . . . . . . . . . . 29

3 Most Commonly used Models for Repairable Systems 31
  3.1 Perfect repair and minimal repair models . . . . . . . . . . . . . . 31
  3.2 Models for repairable systems . . . . . . . . . . . . . . . . . . . . 33
    3.2.1 Homogeneous Poisson process . . . . . . . . . . . . . . . . . 33
    3.2.2 Renewal process . . . . . . . . . . . . . . . . . . . . . . . 35
    3.2.3 Non-homogeneous Poisson process . . . . . . . . . . . . . . 36
    3.2.4 Power law process (PLP) . . . . . . . . . . . . . . . . . . . 39
    3.2.5 Non-homogeneous Poisson processes with bounded mean
        value function . . . . . . . . . . . . . . . . . . . . . . . . . 41
    3.2.6 Trend-renewal process (TRP) . . . . . . . . . . . . . . . . . 42
    3.2.7 Weibull-power law TRP . . . . . . . . . . . . . . . . . . . . 43

4 Parameter Estimation in Non-homogeneous Poisson Process with
  Power Law Intensity Function 49
  4.1 Likelihood function for stochastic processes . . . . . . . . . . . . 49
  4.2 Maximum likelihood estimators in a PLP . . . . . . . . . . . . . . 51
  4.3 Expected number of failures . . . . . . . . . . . . . . . . . . . . 54

5 Estimation of Parameters for Trend-renewal Processes 55
  5.1 Introduction . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 55
  5.2 Likelihood function for a TRP . . . . . . . . . . . . . . . . . . . . 56
  5.3 Estimation in the Weibull-Power Law TRP . . . . . . . . . . . . . 57
    5.3.1 Likelihood function . . . . . . . . . . . . . . . . . . . . . . 57
    5.3.2 ML estimators . . . . . . . . . . . . . . . . . . . . . . . . . 58
  5.4 The alternative methods of estimating trend parameters of a TRP 60
    5.4.1 The least squares (LS) method . . . . . . . . . . . . . . . . 61
    5.4.2 The constrained least squares (CLS) method . . . . . . . . . 61
    5.4.3 The method of moments (M) . . . . . . . . . . . . . . . . . 62

6.10 The overall simulation results. 90
6.11 The ML, LS and CLS estimates of $\alpha$ and $\beta$. 91
6.12 The ML and CLS estimates of $\alpha$ and $\beta$ and their measures of variability. 91
6.13 The overall simulation results. 91
6.14 The ML, LS and CLS estimates of $\alpha$ and $\beta$. 92
6.15 The ML and CLS estimates of $\alpha$ and $\beta$ and their measures of variability. 92
6.16 The LS and CLS estimates of $\alpha$ and $\beta$ when the ML estimator does not exist, whereas the (C)LS estimator does exist. 92
1.1 Functions characterizing lifetime distributions

1.1.1 Survival function

Let $T$ be a non-negative valued random variable determining, for example, a working time of a device (or unit). Such random variable is called the lifetime or survival time. Let $F(t)$ denote the cumulative distribution function (cdf) of the random variable $T$.

**Definition 1.1.1** The function

$$S(t) = P(T > t) = 1 - F(t)$$

is called a reliability function or survival function. Reliability of a unit at time $t$ is defined as the probability that the working time of this unit is greater than $t$.

1.1.2 Failure rate function

Assume that $T$ is a continuous type random variable with density function $f(t)$.

**Definition 1.1.2** The function defined by the formula

$$\rho(t) = \frac{f(t)}{1 - F(t)} = \frac{f(t)}{S(t)} = \frac{S'(t)}{S(t)}$$  \hspace{1cm} (1.1)

is called the failure rate function.
The failure rate function is also called the **hazard function** or **hazard rate**. The failure rate function at time $t$ is the density of the probability distribution of the lifetime of a unit, given the lifetime is greater than $t$:

$$
\rho(t) = \lim_{\Delta t \to 0} \frac{P(t < T \leq t + \Delta t)}{\Delta t P(T > t)} = \lim_{\Delta t \to 0} \frac{f(t) \Delta t + o(\Delta t)}{\Delta t [1 - F(t)]} = \lim_{\Delta t \to 0} \left[ \rho(t) + \frac{o(\Delta t)}{\Delta t} \right].
$$

The failure rate function has the following interpretation: if at time $t_0 = 0$ a unit is included in a system to work, and it then works without failure until time $t$, then the probability that it fails in the interval $(t, t + \Delta t]$ one can estimate by $\rho(t) \Delta t$.

Under the assumption that $S(t) > 0$, it follows from formula (1.1) that

$$
S(t) = \exp \left( - \int_0^t \rho(u) du \right), \quad t \geq 0.
$$

Thus an integrable function $\rho(t)$ is the failure rate function if and only if

$$
\rho(t) \geq 0, \quad t \geq 0, \quad \int_0^\infty \rho(t) dt = \infty.
$$

(1.2)
The failure rate function for the \textit{exponential distribution} (p. 13) $\mathcal{E}(\lambda)$ is the constant function $\rho(t) = 1/\lambda$. For the \textit{Weibull distribution} (p. 17) $\text{We}(\alpha, \beta)$ the failure rate function is of the form $\rho(t) = \alpha \beta^{-\alpha} t^{\alpha-1}$ (see Table 1.1).

Table 1.1: Failure rate functions for some continuous distributions

The function $\gamma(x, \alpha)$ appearing in the formula for the failure rate function in the \textit{gamma distribution} (p. 19) in Table 1.1 denotes the so called modified incomplete gamma function.

**Definition 1.1.3** The function

$$H(t) = \int_0^t \rho(u) du = -\ln[S(t)]$$

is called \textit{cumulative hazard function}.

### 1.1.3 Mean residual life function

Suppose that a unit has worked without failure up to time $t$, and denote by $T_t$ its residual lifetime up to next failure. Let $S_t$ be the survival function corresponding to $T_t$. We have

$$S_t(u) = P(T_t > u) = P(T > t + u | T > t) = \frac{S(t + u)}{S(t)}.$$  

**Definition 1.1.4** The \textit{mean residual life function} is defined by

$$L_F(t) = \mathbb{E}(T_t) = \int_0^\infty S_t(u) du = \int_0^\infty \frac{S(t + u)}{S(t)} du, \quad t \geq 0.$$
We then have the following relations:

\[ L_{\infty}(0) = E(T), \]
\[ \rho(t) = \frac{1 + L_{\infty}'(t)}{L(t)}. \]

1.2 Classification of lifetime distributions in terms of ageing

In this section we present a classification of lifetime distributions which is based on monotonicity property of the failure rate function \( \rho(\cdot) \). Such classification is useful to survival and reliability analysis.

1.2.1 Increasing and decreasing failure rate classes

Definition 1.2.5 A lifetime \( X \) is said to have \text{increasing failure rate (IFR)}, or the distribution of \( X \) is said to belong to the class IFR, if the failure rate function \( \rho(x) \) is increasing for \( x \geq 0 \).

Example 1.2.1 Consider the Gompertz-Makeham distribution. This distribution is defined by the density function

\[ f(x) = (\alpha e^{\beta x} + \lambda) \exp\left[-\lambda x - \frac{\alpha}{\beta}(e^{\beta x} - 1)\right], \quad x \in \mathbb{R}^+, \]

\( \alpha > 0, \beta > 0, \lambda > 0 \). The corresponding cdf is given by

\[ F(x) = 1 - \exp\left[-\lambda x - \frac{\alpha}{\beta}(e^{\beta x} - 1)\right], \]

and the corresponding failure rate function is

\[ \rho(x) = \alpha e^{\beta x} + \lambda. \]

The Gompertz-Makeham law states that the death rate is the sum of an age-independent component (the Makeham term) and an age-dependent component (the Gompertz function) which increases exponentially with age. In a protected environment where external causes of death are rare (laboratory conditions, low mortality countries, etc.), the age-independent mortality component is often negligible. In this case the formula simplifies to a Gompertz law of mortality. The Gompertz law is the same as a Fisher-Tippett distribution for the negative
of age, restricted to negative values for the random variable (positive values for age).

\[ \rho(x) \]

\begin{figure}
\centering
\includegraphics[width=\textwidth]{hazard_rate_functions}
\caption{Hazard rate functions of the Gompertz-Makeham distribution.}
\end{figure}

Analogously, a lifetime \( X \) is said to have decreasing failure rate (DFR), or the distribution of \( X \) is said to belong to the DFR class, if \( \rho(x) \) is non-increasing for \( x \geq 0 \).

Examples of IFR distributions are the Weibull distribution \( \text{We}(\alpha, \beta) \) for \( \alpha > 1 \) and the gamma distribution \( \mathcal{G}(\alpha, \lambda) \) for \( \alpha > 1 \). For \( \alpha < 1 \), these distributions belong to the DFR class.

The exponential distribution \( \mathcal{E}(\lambda) \) has the constant failure rate function \( \rho(x) = 1/\lambda \) and it is the IFR as well as the DFR distribution. If a lifetime has a constant failure rate function we say that we observe no ageing.

If a lifetime of units has an IFR distribution, then we say that the units are ageing and we deal with an ageing process or with positive ageing.

If a lifetime of units has an DFR distribution, then we say that the units are running in and we deal with an improvement process or with negative ageing.

**Definition 1.2.6** A lifetime \( X \) is said to have a distribution with increasing failure rate on the average (IFRA), or the distribution of \( X \) is said to belong
to the class IFRA, if the function \( H(x)/x \) is non-decreasing for \( x > 0 \), where \( H(x) \) denotes the cumulative hazard function.

The class DFRA is defined in an analogous way.

**Theorem 1.2.1** If \( F \) is the cdf of a continuous type random variable \( X \) and \( F(0-) = 0 \), then \( X \) has the IFRA distribution if and only if

\[
S(bx) \geq [S(x)]^b, \tag{1.3}
\]

for \( x > 0, 0 < b < 1 \).

For the DFRA distribution, the reverse inequality sign in (1.3) holds.

### 1.2.2 New better than used and new worse than used classes

A wider class than the distribution class IFR (IFRA) or DFR (DFRA) is the class new better than used.

**Definition 1.2.7** A non-negative valued random variable \( X \) is said to have new better than used (NBU) distribution if

\[
P(X \geq x + y | X \geq x) \leq P(X \geq y), \quad x, y \geq 0.
\]

This means that if \( X \) is the lifetime of a unit, then it has NBU distribution if for all \( x, y \geq 0 \) the probability that the unit which worked without failure up to time \( x \), it will work further without failure in the time interval of length at least \( y \), is less or equal to the probability that a new unit will work without failure in the time interval of length at least \( y \).

If \( F \) is a cdf of a continuous type random variable \( X \) with \( F(0-) = 0 \), then \( X \) has the NBU distribution if

\[
S(x + y) \leq S(x)S(y) \quad \text{for all} \quad x, y \geq 0.
\]

An analogous to the NBU class is the class of new worse than used (NWU) distributions.

The following implications holds between the failure rate classes:

\[
\text{IFR} \implies \text{IFRA} \implies \text{NBU},
\]
\[
\text{DFR} \implies \text{DFRA} \implies \text{NWU}.
\]
1.2.3 Bathtub-shaped failure rate functions

The bathtub-shaped failure rate functions are widely used in reliability systems. A formal definition of a bathtub-shaped failure rate is:

**Definition 1.2.8** A failure rate function \( \rho(x) \) is said to have a bathtub shape if there exist \( x_1 \) and \( x_2 \) such that \( 0 \leq x_1 \leq x_2 \leq \infty \) and

\[
\rho(x) = \begin{cases} 
\text{strictly decreases if} & 0 \leq x \leq x_1, \\
\text{almost constant if} & x_1 \leq x \leq x_2, \\
\text{strictly increases if} & x \geq x_2. 
\end{cases} 
\] (1.4)

The points \( x_1 \) and \( x_2 \) are called the first and second change points, respectively. The time interval \([0, x_1]\) is called the infant mortality period; the interval \([x_1, x_2]\), where \( \rho(x) \) is (almost) flat and attains its minimum value, is called the normal operating life or the useful life; and the interval \([x_2, \infty]\) is called the wear-out period. In other words, the bathtub curve describes a particular form of the hazard function which comprises three parts: the first part is a decreasing failure rate, known as early failures; the second part is an almost constant failure rate, known as normal failures; the third part is an increasing failure rate, known as wear-out failures. The name is derived from the cross-sectional shape of a bathtub.
The bathtub curve is generated by mapping the rate of early "infant mortality" failures when first introduced, the rate of random failures with constant failure rate during its "useful life", and finally the rate of "wear out" failures as the product exceeds its design lifetime.

In less technical terms, in the early life of a product adhering to the bathtub curve, the failure rate is high but rapidly decreasing as defective products are identified and discarded, and early sources of potential failure such as handling and installation error are surmounted. In the mid-life of a product – generally, once it reaches consumers – the failure rate is low and constant. In the late life of the product, the failure rate increases, as age and wear take their toll on the product. Many consumer products strongly reflect the bathtub curve, such as computer processors.

While the bathtub curve is useful, not every product or system follows a bathtub curve hazard function, for example if units are retired or have decreased use during or before the onset of the wear-out period, they will show fewer failures per unit calendar time (not per unit use time) than the bathtub curve.

Let us consider some examples of bathtub-type hazard rate functions.
Example 1.2.2 Let a lifetime $X$ have the cdf defined by

$$F(x) = 1 - e^{\lambda(1-e^{-\beta} x)} \quad (x > 0),$$

where $\lambda > 0$ and $\beta > 0$ are the parameters. This type of distribution was considered by Chen (2000) and we call it the Chen distribution. The corresponding failure rate function of this distribution is

$$\rho(x) = \lambda \beta x^{\beta-1} e^{x \beta} \quad (x > 0).$$

Since

$$\rho'(x) = \lambda \beta x^{\beta-2} e^{x \beta} \left[(\beta - 1) + \beta x^\beta\right] \quad (x > 0),$$

$\rho(x)$ may have a bathtub shape when $\beta < 1$. The distribution has increasing failure rate function when $\beta \geq 1$. Figures 1.4 and 1.5 show the failure rate functions for various values of $\lambda$ and $\beta$. □

Figure 1.4: Hazard rate functions of the Chen distribution for some $\lambda \geq 1$. 
Example 1.2.3 Lai et al. (2003) introduced a modified Weibull distribution, defined by the following form of cdf:

$$F(x) = 1 - \exp \left( -\alpha x^\beta e^{\lambda x} \right),$$

where $\alpha > 0$, $\beta \geq 0$, $\lambda > 0$ are the parameters. The corresponding hazard rate function is given by the formula

$$\rho(t) = \alpha (\beta + \lambda x)x^{\beta-1}e^{\lambda x},$$

which has a turning point (i.e., minimum) at $x^* = (\sqrt{\beta} - \beta)/\lambda$ for $\beta < 1$. $\Box$
Figure 1.6: Hazard rate functions of a modified Weibull distribution.
Chapter 2

Parametric Families of Lifetime Distributions

2.1 Gamma family

2.1.1 Exponential distribution

A random variable $X$ is said to have exponential distribution with parameter $\lambda$ ($\lambda > 0$), which will be denoted by $\mathcal{E}(\lambda)$, if its density is defined by

$$f(x) = f(x; \lambda) = \frac{1}{\lambda} \exp \left(-\frac{x}{\lambda}\right) 1_{(0,\infty)}(x).$$

The cumulant distribution function is of the form

$$F(x) = \left[1 - \exp \left(-\frac{x}{\lambda}\right)\right] 1_{(0,\infty)}(x).$$

The characteristic function is

$$\phi(t) = \frac{1}{1 - \lambda t}.$$

The $k$-th moment of the random variable $X$ is defined by $E(X^k) = \lambda^k k!$. In particular,

$$E(X) = \lambda, \quad \text{Var}(X) = \lambda^2.$$

The mode and median are zero and $\lambda \ln 2$, respectively, the skewness $\gamma_1 = 2$ and the excess $\gamma_2 = 6$.

The exponential distribution $\mathcal{E}(\lambda)$ is a special case of the gamma distribution, the Weibull distribution and the negative exponential distribution (p. 14). Namely, it is the $\mathcal{G}(1, \lambda)$, $\mathcal{We}(1, \lambda)$ and $\mathcal{NE}(0, \lambda)$ distribution.
If \(X_1, \ldots, X_n\) are independent and identically exponential \(\mathcal{E}(\lambda)\) distributed, then \(\sum_{i=1}^{n} X_i\) has the \(\triangleright\) gamma distribution \(\mathcal{G}(n, \lambda)\) which is equivalent to the \(\triangleright\) Erlang distribution \(\mathcal{E}_r(n, \lambda)\).

In the class of continuous distributions, the exponential distribution is the only one having the following property

\[
P(X > s + t | X > s) = P(X > t), \quad s > 0, t > 0,
\]

which is called the lack of memory property. Interpreting the random variable \(X\) as a lifetime of a unit, the lack of memory property asserts that, independently of the current working time, the future working time is independent of the past and has the same distribution as the common distribution of the working time of the unit. This property plays an important role in theory of stochastic processes, especially in renewal theory and in theory of mass service and reliability.

### 2.1.2 Negative exponential distribution

A random variable \(X\) is said to have the negative exponential distribution with location parameter \(\mu\) and scale parameter \(\sigma\) \((\mu \in \mathbb{R}, \sigma > 0)\), which we denote by \(\mathcal{NE}(\mu, \sigma)\), if its density is of the form

\[
f(x) = f(x; \mu, \sigma) = \frac{1}{\sigma} \exp \left( -\frac{x - \mu}{\sigma} \right) 1_{(\mu, \infty)}(x). \tag{2.1}
\]

The cdf is defined by

\[
F(x) = \left[ 1 - \exp \left( -\frac{x - \mu}{\sigma} \right) \right] 1_{(\mu, \infty)}(x).
\]

The negative exponential distribution is also called the two-parameter exponential distribution or location and scale exponential distribution.
The characteristic function is of the form
\[ \phi(t) = \frac{e^{it\mu}}{1 - it\sigma}. \]

The expected value and the variance of the negative exponential distribution \( \mathcal{NE}(\mu, \sigma) \) are equal to
\[ E(X) = \mu + \sigma, \quad \text{Var}(X) = \sigma^2, \]
respectively.

There are many applications of the statistical model defined by (2.1) in reliability and lifetime examinations. The parameter \( \mu \) is often interpreted as a threshold value of a minimal lifetime and it is then natural to assume that \( \mu > 0 \). If \( \mu \geq 0 \), then the negative exponential distribution is called the left truncated exponential distribution. In the case \( \mu = 0 \) the \( \mathcal{NE}(\mu, \sigma) \) distribution becomes the exponential distribution \( \mathcal{E}(\sigma) \).

### 2.1.3 Erlang distribution

A random variable \( X \) is said to have the Erlang distribution with parameters \( k \) and \( \mu \) (\( k \in \mathbb{N}, \mu > 0 \)), which will be denoted by \( \mathcal{E}\!r(k, \mu) \), if its density has the following form
\[
f(x) = \frac{1}{\mu^k(k-1)!} x^{k-1} \exp\left(-\frac{x}{\mu}\right) 1_{(0,\infty)}(x).
\]
The expected value and the variance are equal to
\[ E(X) = k\mu, \quad \text{Var}(X) = k\mu^2, \]
respectively.

The Erlang distribution is a special case of the \textit{gamma distribution} (p. 19), namely it is equivalent to the gamma distribution \( \mathcal{G}(k, \mu) \) for \( k \in \mathbb{N} \). When \( k = 1 \), the distribution \( \mathcal{E}(k, \mu) \) becomes the exponential distribution \( \mathcal{E}(\mu) \).

The distribution of the total lifetime until \( k \) events of the Poisson process with intensity \( \lambda = 1/\mu \) have been observed has the Erlang distribution \( \mathcal{E}(k, \mu) \). The Erlang distribution is used in the theory of mass service and in examination of service times and incoming streams.

### 2.1.4 Rayleigh distribution

A random variable \( X \) is said to have \textit{Rayleigh distribution} with parameter \( \sigma \) (\( \sigma > 0 \)), which will be denoted by \( \mathcal{R}(\sigma) \), if its density is defined by
\[
f(x) = f(x; \sigma) = \frac{x}{\sigma^2} \exp\left(-\frac{x^2}{2\sigma^2}\right) 1_{(0, \infty)}(x).
\]
The cdf has the form
\[
F(x) = \left\{1 - \exp\left(-\frac{x^2}{2\sigma^2}\right)\right\} 1_{(0, \infty)}(x).
\]
The parameter \( \sigma \) is the scale parameter.

The moments of order \( k \) are
\[
E(X^k) = 2^{k/2}\sigma^k \Gamma\left(\frac{k}{2} + 1\right)
\]
(\( \Gamma \) denotes the gamma function). In particular,
\[
E(X) = \sqrt{\frac{\pi}{2}} \sigma \approx 1.25331\sigma, \quad \text{Var}(X) = \left(2 - \frac{\pi}{2}\right)\sigma^2 \approx 0.429204\sigma^2.
\]
The mode and the median are equal to \( \sigma \) and \( \sqrt{2\ln 2}\sigma \approx 1.17741\sigma \), respectively.
The Rayleigh distribution is a special case of the Weibull distribution, namely it is equivalent to the $We(2, \sqrt{2}\sigma)$ distribution. It is used first of all in reliability theory.

2.1.5 Weibull distribution

A random variable $X$ is said to have Weibull distribution with parameters $\alpha$ and $\beta$ ($\alpha > 0, \beta > 0$), which will be denoted by $We(\alpha, \beta)$, if its density is of the form

$$f(x) = f(x; \alpha, \beta) = \alpha \beta^{-\alpha} x^{\alpha-1} \exp\left[ - \left( \frac{x}{\beta} \right)^\alpha \right] 1_{(0,\infty)}(x)$$

$$= \frac{\alpha}{\beta} \left( \frac{x}{\beta} \right)^{\alpha-1} \exp\left[ - \left( \frac{x}{\beta} \right)^\alpha \right] 1_{(0,\infty)}(x).$$

The parameter $\alpha$ is the shape parameter, and the parameter $\beta$ is the scale parameter. The cdf of the Weibull distribution $We(\alpha, \beta)$ is

$$F(x) = \left\{ 1 - \exp \left[ - \left( \frac{x}{\beta} \right)^\alpha \right] \right\} 1_{(0,\infty)}(x).$$
The moments are defined by

$$E(X^k) = \beta^k \Gamma \left( 1 + \frac{k}{\alpha} \right).$$

In particular,

$$E(X) = \beta \Gamma \left( 1 + \frac{1}{\alpha} \right), \quad \text{Var}(X) = \beta^2 \left[ \Gamma \left( 1 + \frac{2}{\alpha} \right) - \Gamma^2 \left( 1 + \frac{1}{\alpha} \right) \right]$$

($\Gamma$ denotes the gamma function). The mode and the median are equal to 0 and $\beta (\ln 2)^{1/\alpha}$, respectively.

The moment generating function of the random variable $Y = \ln X$, when $X$ has the Weibull distribution $\text{We}(\alpha, 1)$, is defined by

$$E \left( e^{t \ln X} \right) = E(X^t) = \Gamma \left( 1 + \frac{t}{\alpha} \right).$$

Special cases of the Weibull distribution are:

- $\text{We}(1, \lambda) \quad \Rightarrow$ exponential distribution $\mathcal{E}(\lambda);
- \text{We}(2, \sqrt{2} \sigma) \quad \Rightarrow$ Rayleigh distribution $\mathcal{Ra}(\sigma)$. 
If $X$ has the $\text{We}(\alpha, \beta)$ distribution, then the random variable $Y = -\ln X$ has a $\triangleright$ double exponential distribution (p. 21) $\text{DE}(-\ln \beta, 1/\alpha)$ (i.e. the $\triangleright$ extreme value distribution of type I (p. 23)), and the random variable $-X$ has the $\triangleright$ extreme value distribution of type III (p. 24) with parameter $\alpha$.

The Weibull distribution one obtains as a limit distribution of the minimum of independent and identically distributed random variables. It finds important applications in reliability theory by description of failure-free working times of devices.

### 2.1.6 Three-parameter Weibull distribution

A more general form of the Weibull distribution is the three-parameter Weibull distribution with additional location parameter $x_0$ ($x_0 \in \mathbb{R}$). We deal with such distribution if the random variable $X - x_0$ has the usual two-parameter Weibull distribution.

### 2.1.7 Gamma distribution

A random variable $X$ is said to have gamma distribution with parameters $\alpha$ and $\lambda$ ($\alpha > 0, \lambda > 0$), which will be denoted by $\text{G}(\alpha, \lambda)$, if its density is of the form

$$f(x) = f(x; \alpha, \lambda) = \frac{1}{\lambda^\alpha \Gamma(\alpha)} x^{\alpha-1} \exp \left( -\frac{x}{\lambda} \right) 1_{(0,\infty)}(x),$$

where $\Gamma(\alpha)$ is the gamma function. The parameter $\alpha$ is the shape parameter; $\lambda$ is the scale parameter.

The characteristic function is

$$\phi(t) = \frac{1}{(1 - i\lambda t)^\alpha}.$$

The $k$-th moment of the random variable $X$ is defined by

$$E(X^k) = \frac{\lambda^k \Gamma(k + \alpha)}{\Gamma(\alpha)} = \alpha(\alpha + 1) \cdots (\alpha + k - 1) \lambda^k.$$

In particular,

$$E(X) = \alpha \lambda, \ E(X^2) = \alpha(\alpha + 1) \lambda^2, \ \text{Var}(X) = \alpha \lambda^2.$$

Special cases of the gamma distributions are:

- $\text{G}(1, \lambda) \quad \triangleright$ exponential distribution with the parameter $\lambda, \mathcal{E}(\lambda)$;
- $\text{G}(k, \mu) \quad \triangleright$ Erlang distribution with the parameters $(k, \mu), k \in \mathbb{N}, \mu > 0$;
The distribution \( G \left( \frac{n}{2}, 2 \right) \) is called the **chi-square distribution** \((\chi^2)\) with \( n \) degrees of freedom.

### 2.1.8 Three-parameter gamma distribution

A random variable \( X \) is said to have the **three-parameter gamma distribution** with parameters \( \alpha, \lambda \) and \( \gamma \) \((\alpha > 0, \lambda > 0, \gamma > 0)\), if its density is of the form

\[
f(x) = f(x; \alpha, \lambda, \gamma) = \frac{\gamma}{\lambda^{\alpha/\gamma} \Gamma(\alpha/\gamma)} x^{\alpha-1} \exp \left( -\frac{x^{\gamma}}{\lambda} \right) 1_{(0, \infty)}(x).
\]

The parameter \( \lambda \) is the scale parameter, the parameters \( \alpha \) and \( \gamma \) are the shape parameters. This distribution we denote by \( \mathcal{G}am(\alpha, \lambda, \gamma) \). The three-parameter gamma distribution is also called the **generalized gamma distribution**.

Special cases of the generalized gamma distribution are

- \( \mathcal{G}am(\alpha, \lambda, 1) \) – gamma distribution \( \mathcal{G}(\alpha, \lambda) \);
- \( \mathcal{G}am(n/2, 2, 1) \) – chi-square distribution with \( n \) degrees of freedom \( \chi^2(n) \);
- \( \mathcal{G}am(\alpha, \beta^\alpha, \alpha) \) – Weibull distribution \( \mathcal{W}e(\alpha, \beta) \);
- \( \mathcal{G}am(2, 2\sigma^2, 2) \) – Rayleigh distribution \( \mathcal{R}a(\sigma) \).

### 2.1.9 Four-parameter generalized gamma distribution

A random variable \( X \) is said to have the **four-parameter generalized gamma distribution** with parameters \( \alpha, \lambda, \mu \) and \( \gamma \) \((\alpha > 0, \lambda > 0, \mu \in \mathbb{R}, \gamma > 0)\), if its density has the following form:

\[
f(x) = f(x; \alpha, \lambda, \gamma, \mu) = \frac{\gamma}{\lambda^{\alpha/\gamma} \Gamma(\alpha/\gamma)} (x - \mu)^{\alpha-1} \exp \left[ -\frac{(x - \mu)^\gamma}{\lambda} \right] 1_{(\mu, \infty)}(x).
\]

We denote this distribution by \( \mathcal{G}am_4(\alpha, \lambda, \mu, \gamma) \). When \( \mu = 0 \) one obtains the density of the generalized gamma distribution, i.e. \( \mathcal{G}am_4(\alpha, \lambda, 0, \gamma) = \mathcal{G}am(\alpha, \lambda, \gamma) \). A random variable \( X \) has the four-parameter generalized gamma distribution \( \mathcal{G}am_4(\alpha, \lambda, \mu, \gamma) \) if and only if the random variable \( X - \mu \) has the generalized (three-parameter) gamma distribution \( \mathcal{G}am(\alpha, \lambda, \gamma) \).

### 2.2 Inverse gamma distribution

A random variable \( X \) is said to have **inverse gamma distribution** with parameters \( \alpha \) and \( \lambda \) \((\alpha > 0, \lambda > 0)\), which will be denoted by \( \mathcal{I}gam(\alpha, \lambda) \), if its density has
the following form
\[ f(x) = f(x; \alpha, \lambda) = \frac{1}{\lambda^\alpha \Gamma(\alpha)} x^{-\alpha-1} \exp\left(-\frac{1}{\lambda x}\right) 1_{(0,\infty)}(x). \]

The expected value and the variance are given by
\[ E(X) = \frac{1}{(\alpha - 1)\lambda}, \text{ jeżeli } \alpha > 1; \quad \text{Var}(X) = \frac{1}{(\alpha - 1)^2(\alpha - 2)\lambda^2}, \text{ jeżeli } \alpha > 2, \]
respectively. The random variable \(1/X\) has the \( \triangleright \) gamma distribution (p. 19) \( G(\alpha, \lambda) \).

### 2.3 Gompertz distribution

A random variable \( X \) follows the Gompertz distribution with parameters \( \alpha \) and \( \beta \) \((\alpha > 0, \beta > 0)\), denoted by \( \text{Gom}(\alpha, \beta) \), if its density function is defined by
\[ f(x) = \beta e^{\alpha x} \exp\left[\frac{\beta}{\alpha} (1 - e^{\alpha x})\right] 1_{[0,\infty)}(x). \]

This distribution was introduced by Gompertz in 1825 to describe mortality curves.

### 2.4 Gumbel distributions

#### 2.4.1 Double exponential distribution

A random variable \( X \) is said to have double exponential distribution with location parameter \( \mu \) and scale parameter \( \sigma \) \((\mu \in \mathbb{R}, \sigma > 0)\), which will be denoted by \( \text{DE}(\mu, \sigma) \), if its density function has the following form:
\[ f(x) = f(x; \mu, \sigma) = \frac{1}{\sigma} \exp\left[ - \exp\left( - \frac{x - \mu}{\sigma} \right) - \frac{x - \mu}{\sigma} \right] \]
\[ = \frac{1}{\sigma} \exp\left( - \frac{x - \mu}{\sigma} \right) \exp\left[ - \exp\left( - \frac{x - \mu}{\sigma} \right) \right], \quad x \in \mathbb{R}. \]

The cdf is defined by
\[ F(x) = \exp\left[ - \exp\left( - \frac{x - \mu}{\sigma} \right) \right]. \]
The characteristic function has the following form:

$$\phi(t) = e^{it \mu} \Gamma(1 - i\sigma t)$$

($\Gamma$ denotes the gamma function).

The expected value and the variance of the $\mathcal{DE}(\mu, \sigma)$ distribution are equal to

$$E(X) = \mu + \sigma C, \quad \text{Var}(X) = \frac{\pi^2 \sigma^2}{6},$$

respectively, where $C = -\Gamma'(1) = 0.57721566490\ldots$ denotes the Euler constant. The skewness of this distribution is $\gamma_1 = 12\sqrt{6}/\zeta(3)/\pi^3 \approx 1.1395$, and the excess $\gamma_2 = 2.4$. The mode and the median are equal to $\mu$ and $\mu - \sigma \ln \ln 2$, respectively.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure2_4.png}
\caption{Density functions of the double exponential distribution $\mathcal{DE}(\mu, \sigma)$}
\end{figure}

If $X$ follows the $\mathcal{DE}(\mu, \sigma)$ distribution, then the random variable $Y = \exp(-X)$ has the Weibull distribution $\mathcal{WE}(1/\sigma, \exp(-\mu))$, which becomes the exponential distribution $\mathcal{E}(\exp(-\mu))$ for $\sigma = 1$. The double exponential distribution is equivalent to the $\triangleright$ extreme value distribution of type I (p. 23). For this reason the double exponential distribution is often called the extreme value distribution or the Gumbel distribution $\mathcal{Gum}(\mu, \sigma)$.

The double exponential distribution is used in reliability theory and among others in evaluating maximal precipitations, water levels and earthquakes.
2.4.2 Generalized Gumbel distribution

The generalized Gumbel distribution is usually meant as the generalized extreme value distribution (p. 24) \( GEV(\mu, \sigma, \gamma) \). The name of generalized Gumbel distribution is often referred to the following slight modification of the generalized extreme value distribution. A random variable \( X \) is said to have the generalized Gumbel distribution with parameters \( \mu, \sigma \) and \( \nu \) \( (\mu \in \mathbb{R}, \sigma > 0, \nu \in \mathbb{R}\setminus\{0\}) \), if its density function has the following form:

\[
\begin{align*}
    f(x) &= f(x; \mu, \sigma, \nu) \\
    &= \begin{cases} \\
        \frac{1}{\sigma} \left(1 + \frac{x - \mu}{\sigma}\right)^{(1/\nu)-1} \exp \left[-\left(1 + \frac{x - \mu}{\sigma}\right)^{1/\nu}\right] 1_{(\mu - \sigma/\nu, \infty)}(x), & \nu > 0, \\
        \frac{1}{\sigma} \left(1 + \frac{x - \mu}{\sigma}\right)^{(1/\nu)-1} \exp \left[-\left(1 + \frac{x - \mu}{\sigma}\right)^{1/\nu}\right] 1_{(-\infty, \mu - \sigma/\nu)}(x), & \nu < 0.
    \end{cases}
\end{align*}
\]

The distribution defined above we denote by \( GGum(\mu, \sigma, \nu) \). In the limit case, when \( \nu \to 0 \), one obtains the Gumbel distribution \( Gum(\mu, \sigma) \) (generalized extreme value distribution (p. 23)).

A random variable \( X \) has the \( GGum(\mu, \sigma, \nu) \) distribution when

\[
(1 + \nu \frac{x - \mu}{\sigma})^{1/\nu} \sim \mathcal{E}(1).
\]

2.4.3 Extreme value distribution

Let \( X_1, X_2, \ldots \) be a sequence of independent and identically distributed random variables with a cdf \( F(x) \). Denote \( W_n = \max\{X_1, \ldots, X_n\} \) and let \((a_n), (b_n), b_n > 0, n = 1, 2, \ldots,\) be sequences of real numbers. If the sequence of random variables \( Y_n = (W_n - a_n)/b_n \) converges in law to a random variable \( X \) with non-degenerated distribution defined by a cdf \( G \), then \( G \) can take only one of the following form

(1) extreme value distribution of type I:

\[
G_1(x) = \exp \left[-\exp \left(-\frac{x - \mu}{\sigma}\right)\right], \quad x \in \mathbb{R};
\]

(2) extreme value distribution of type II:

\[
G_2(x) = \exp \left[-\left(\frac{x - \mu}{\sigma}\right)^{-\alpha}\right] 1_{[\mu, \infty)}(x);
\]
(3) **Extreme value distribution of type III:**

\[ G_3(x) = \begin{cases} 
\exp \left[ - \left( \frac{x - \mu}{\sigma} \right) ^ \alpha \right] & \text{for } x \leq \mu, \\
1 & \text{for } x > \mu, 
\end{cases} \]

where \( \mu \in \mathbb{R} \), \( \sigma > 0 \) and \( \alpha > 0 \) are parameters. The corresponding distributions of the random variable \(-X\) are also called the extreme value distributions.

The existence of the sequences \((a_n),(b_n),b_n > 0,n = 1,2,\ldots\), such that the cdf’s of the random variables \(Y_n\) converge to a cdf of non-degenerated distribution, as well as the type of the limit distribution determined by \( G \) depends on the cdf \( F \).

The extreme value distribution of type I is called the **Gumbel distribution**. We denote this distribution by \( G \text{um}(\mu,\sigma) \). The distributions of type II and III can be come down to the \( G \text{um}(\mu,\sigma) \) distribution by using the simple transformations \( Z = \log(X - \mu) \) and \( Z = -\log(X - \mu) \). Because of this, all the types of distributions above are often called the Gumbel distributions. The extreme value distribution of type II is also the **Fréchet distribution**.

The extreme value distribution of type I corresponds to the **double exponential distribution** (p. 21). If \( X \) has the distribution of type I, then \( Z = \exp[-(X - \mu)/\sigma] \) follows the exponential distribution \( \mathcal{E}(1) \). If \( Y \) has the extreme value distribution of type III, then the cdf of \(-Y\) is defined by \( x \mapsto 1 - G_3(-x) \), which leads to the **Weibull distribution** (p. 17).

The extreme value distributions and their generalizations (\( \triangleright \) *generalized extreme value distribution* (p. 24)) have applications among others in natural phenomena analysis (such as rapid heavy rains, floods, hurricanes, earthquakes, air pollution, corrosion), in reliability analysis and in insurance analysis.

### 2.4.4 Generalized extreme value distribution

A random variable \( X \) is said to have **generalized extreme value distribution** with parameters \( \mu, \sigma \) and \( \gamma \) \((\mu, \gamma \in \mathbb{R}, \sigma > 0)\), if its cdf is defined by

\[
F(x) = F(x;\mu,\sigma,\gamma) = \begin{cases} 
\exp \left[ - \left( 1 - \frac{x - \mu}{\sigma} \right)^{1/\gamma} \right] \mathbf{1}_{(-\infty,\mu+\sigma/\gamma]}(x), & \text{if } \gamma > 0, \\
\exp \left[ - \left( 1 - \frac{x - \mu}{\sigma} \right)^{1/\gamma} \right] \mathbf{1}_{[\mu+\sigma/\gamma,\infty)}(x), & \text{if } \gamma < 0, \\
\exp \left[ - \exp \left( - \frac{x - \mu}{\sigma} \right) \right], & x \in \mathbb{R}, \text{ if } \gamma = 0.
\end{cases}
\]
This distribution we denote by $\mathcal{GEV}(\mu, \sigma, \gamma)$. The case $\gamma < 0$ covers the extreme value distribution of type II; the case $\gamma > 0$ corresponds to the extreme value distribution of type III; the case $\gamma = 0$ leads to the extreme value distribution of type I (the Gumbel distribution).

The density function corresponding to the $\mathcal{GEV}(\mu, \sigma, \gamma)$ distribution has the following form:

$$f(x) = f(x; \mu, \sigma, \gamma)$$

$$= \begin{cases} 
\frac{1}{\sigma} \left( 1 - \gamma \frac{x - \mu}{\sigma} \right)^{(1/\gamma) - 1} \exp \left[ - \left( 1 - \gamma \frac{x - \mu}{\sigma} \right)^{1/\gamma} \right] \mathbb{1}_{(-\infty, \mu + \sigma/\gamma)}(x), & \gamma > 0, \\
\frac{1}{\sigma} \left( 1 - \gamma \frac{x - \mu}{\sigma} \right)^{(1/\gamma) - 1} \exp \left[ - \left( 1 - \gamma \frac{x - \mu}{\sigma} \right)^{1/\gamma} \right] \mathbb{1}_{(\mu + \sigma/\gamma, \infty)}(x), & \gamma < 0, \\
\frac{1}{\sigma} \exp \left( - \frac{x - \mu}{\sigma} \right) \exp \left[ - \exp \left( - \frac{x - \mu}{\sigma} \right) \right], & x \in \mathbb{R}, \quad \gamma = 0.
\end{cases}$$

### 2.5 Lognormal distributions

A random variable $X$ is said to have the lognormal distribution with parameters $\mu$ and $\sigma^2$ ($\mu \in \mathbb{R}, \sigma > 0$), which we denote by $\mathcal{LN}(\mu, \sigma^2)$, if its density function is of the form

$$f(x) = f(x; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi}\sigma x} \exp \left[ - \frac{(\ln x - \mu)^2}{2\sigma^2} \right] \mathbb{1}_{(0, \infty)}(x).$$

The moments of order $k$ ($k = 1, 2, \ldots$) are defined by

$$E(X^k) = \exp \left( \frac{1}{2} k^2 \sigma^2 + k\mu \right).$$

In particular,

$$E(X) = \exp \left( \frac{1}{2} \sigma^2 + \mu \right), \quad \text{Var}(X) = \exp(\sigma^2 + 2\mu) \left( \exp \sigma^2 - 1 \right).$$

The mode is equal to $\exp(\mu - \sigma^2)$, and the median is $\exp(\mu)$. 
A random variable $X$ has the $\mathcal{LN}(\mu, \sigma^2)$ distribution, if $\ln X$ follows the normal distribution $\mathcal{N}(\mu, \sigma^2)$. If $Y$ has the normal distribution $\mathcal{N}(0, 1)$, then $X = \exp(\sigma Y + \mu)$ is $\mathcal{LN}(\mu, \sigma^2)$ distributed.

If $X_1, \ldots, X_k$ are independent random variables with $X_i$ ($i = 1, \ldots, k$) having the $\mathcal{LN}(\mu_i, \sigma_i^2)$ distribution, then $\prod_{i=1}^k a_i X_i$, where $a_i, i = 1, \ldots, k$, are any positive constants, has the lognormal distribution $\mathcal{LN}(\sum_{i=1}^k (\mu_i + \ln a_i), \sum_{i=1}^k \sigma_i^2)$.

The lognormal distribution is used in describing the life data resulting from a single semiconductor failure mechanism or a closely related group of failure mechanisms. This is a suitable model for patients of tuberculosis or other diseases where the potential for death increases early in the disease and then decreases when the effect of the treatment is evident. This distribution is widely applied in statistical examinations in physics, geology, economics and biology.

### 2.6 Pareto family

#### 2.6.1 Pareto distribution

A random variable $X$ is said to have the Pareto distribution with parameters $x_0$ and $\alpha$ ($x_0 > 0, \alpha > 0$), which we denote by $\mathcal{P}a(x_0, \alpha)$, if its density function has
the following form:

$$f(x) = \frac{\alpha}{x_0} \left( \frac{x_0}{x} \right)^{\alpha+1} 1_{(x_0,\infty)}(x).$$

The cdf is defined by

$$F(x) = \left[ 1 - \left( \frac{x_0}{x} \right)^{\alpha} \right] 1_{(x_0,\infty)}(x), \quad x_0 > 0, \alpha > 0.$$ 

The moment generating function of the random variable $Y = \ln X$, when $X$ has the $\mathcal{P}a(x_0, \alpha)$ distribution, is expressed by the formula

$$\psi_Y(t) = E(e^{t \ln X}) = E(X^t) = \frac{\alpha x_0}{\alpha - t}.$$ 

The expectation and the variance of the random variable $X$ are given by

$$E(X) = \frac{\alpha x_0}{\alpha - 1} \text{ for } \alpha > 1, \quad \text{Var}(X) = \frac{\alpha x_0^2}{(\alpha - 1)^2(\alpha - 2)} \text{ for } \alpha > 2,$$

respectively. The median of the random variable $X$ equals $2^{1/\alpha} x_0$. If $X$ has the $\mathcal{P}a(x_0, \alpha)$ distribution, then the random variable $\ln(X/x_0)$ follows the exponential distribution $\mathcal{E}(1/\alpha)$.

The Pareto distributed random variable can take its values only above a positive level $x_0$.

### 2.6.2 Generalized Pareto distribution

The generalized Pareto distribution is defined by the following form of the cdf

$$F(x) = F(x; \beta, \gamma) = \begin{cases} 
1 - \left( 1 - \frac{\gamma x}{\beta} \right)^{1/\gamma} 1_{(0,\beta/\gamma)}(x), & \text{gdy } \gamma > 0, \\
1 - \left( 1 - \frac{\gamma x}{\beta} \right)^{1/\gamma} 1_{(0,\infty)}(x), & \text{gdy } \gamma < 0, \\
1 - e^{-x/\beta} 1_{(0,\infty)}(x), & \text{gdy } \gamma = 0,
\end{cases}$$

where $\beta > 0$. This distribution we denote by $\mathcal{GP}a(\beta, \gamma)$. The density function of the $\mathcal{GP}a(\beta, \gamma)$ distribution has the form

$$f(x) = f(x; \beta, \gamma) = \begin{cases} 
\frac{1}{\beta} \left( 1 - \frac{\gamma x}{\beta} \right)^{(1/\gamma)-1} 1_{(0,\beta/\gamma)}(x), & \text{gdy } \gamma > 0, \\
\frac{1}{\beta} \left( 1 - \frac{\gamma x}{\beta} \right)^{(1/\gamma)-1} 1_{(0,\infty)}(x), & \text{gdy } \gamma < 0, \\
\frac{1}{\beta} e^{-x/\beta} 1_{(0,\infty)}(x), & \text{gdy } \gamma = 0.
\end{cases}$$
Let us note that for $\gamma = 0$ this is the exponential distribution with mean $\beta$, and for $\gamma = 1$ this is the uniform distribution on the interval $(0, \beta)$, i.e. $\mathcal{GP}(\beta, 0) = \mathcal{E}(\beta)$ and $\mathcal{GP}(\beta, 1) = \mathcal{U}(0, \beta)$.

If $X \sim \mathcal{GP}(\beta, \gamma)$, then the random variable $X - u$, under the condition $X > u$, has the generated Pareto distribution $\mathcal{GP}(\beta - \gamma u, \gamma)$, given $\beta - \gamma u > 0$. This property is called **threshold-stability** (compare with the lack of memory property of the exponential distribution).

The failure rate function (p. 1) of the $\mathcal{GP}(\beta, \gamma)$ distribution has the form $\rho(x) = \frac{\beta - \gamma x}{\beta}$. Thus, this is the IFR distribution for $\gamma > 0$, and the DFR distribution for $\gamma < 0$. For $\gamma = 0$ this is the IFR as well as the DFR distribution.

If $1 + \gamma k > 0$, then there exists the moment of order $k$ of the random variable $X$ distributed according to $\mathcal{GP}(\beta, \gamma)$, and it is defined by the formula

$$E\left[\left(1 - \frac{\gamma X}{\beta}\right)^k\right] = \frac{1}{1 + \gamma k}.$$

In particular,

$$E(X) = \frac{\beta}{1 + \gamma}, \quad \text{Var}(X) = \frac{\beta^2}{(1 + \beta)(1 + 2\beta)}.$$

### 2.7 Burr distributions

From among the distributions belonging to the family of *Burr distributions* we present the following ones:

1. The distribution $B_{u(1)}(\lambda, \mu)$ with shape parameters $\lambda$ and $\mu$ ($\lambda > 0, \mu > 0$), whose density function is defined by

$$f(x) = \lambda \mu x^{\lambda-1} (1 + x^\lambda)^{-(\mu+1)} 1_{(0,\infty)}(x);$$

2. The distribution $B_{u(2)}(\lambda, \mu)$ with parameters $\lambda$ and $\mu$ ($\lambda > 0, \mu > 0$), whose density function is defined by

$$f(x) = \lambda \mu x^{\lambda-1} (\mu + x^\lambda)^{-2} 1_{(0,\infty)}(x).$$

The cdf of the $B_{u(2)}(\lambda, \mu)$ distribution has the form

$$F(x) = \frac{x^\lambda}{\mu + x^\lambda} 1_{(0,\infty)}(x).$$
2.8 Time-transformed exponential family

Consider the exponential family of distributions with the following density

\[ f(x; \omega) = s'(x)\omega \exp[-\omega s(x)]1_{(\mu,\infty)}(x), \]

where \( s(x) \) is strictly increasing and differentiable with \( s(\mu) = 0 \). The cumulative distribution function is of the form

\[ F(x; \omega) = \{1 - \exp[-\omega s(x)]\}1_{(\mu,\infty)}(x). \]

The parameter \( \omega \) is unknown and \( \mu \) is known. This exponential family covers many distributions serving as lifetime distributions in reliability models. Some of important members of this family are contained in Table 2.1.

Chapter 3

Most Commonly used Models for Repairable Systems

3.1 Perfect repair and minimal repair models

Let $N(t)$ denote the number of failures (events) in the time interval $(0, t]$ and let $T_i$ be the time of the $i$th failure. The times $T_i$ are called failure times or event times. Define $T_0 = 0$ and denote $X_i = T_i - T_{i-1}$, $i = 1, 2, \ldots$, – the time between failure number $i - 1$ and failure number $i$. The times $X_i$ are called working times or waiting times and also inter-arrival times.

The observed sequence $\{T_i, i = 1, 2, \ldots\}$ of occurrence times $T_1, T_2, \ldots$ (failure times) forms a point process, and $\{N(t), t \geq 0\}$ is the corresponding counting process.

Following Ascher and Feingold (1984), a repairable system is defined to be a system which, after failing to perform one or more of its functions satisfactorily, can be restored to fully satisfactory performance by any method, other than replacement of the entire system.

A restoration wherein a failed system (device) is returned to operable condition is called ‘repair’. It could involve replacing failed components by working ones, restoring broken connections, mending it or any part of it by machining, cleaning, lubricating etc.

In the context of failure-repair models it is assumed here that all repair times are equal to 0. In practice this corresponds to the situation, when repair actions are conducted immediately or the repair times can be neglected with comparison to the working times $X_i$.

A repair under which a failed system is replaced with a new identical one is called a perfect repair.
By a **minimal repair** we mean a repair of limited effort wherein the device is returned to the operable state it was in just before failure.

Formal definitions of minimal repair are given below. For a comparison of definitions of this notion, see, for example, Arjas (2002).

A definition of minimal repair used by Sheu (1990) and then by others, e.g., Bagai and Jain (1994), Bae and Lee (2001), uses the survival function as below.

**Definition 3.1.1** If $F$ is a cdf of lifetime distribution of a device, the cdf of lifetime $X$ following a **perfect repair** is always $F$; but the cdf of lifetime distribution following a **minimal repair** performed at age $s$ is given by

$$P(X > t | X > s) = S(t | s) = \frac{S(s + t)}{S(s)}.$$ 

The definition of minimal repair written in a more formal way by Nakagawa and Kowada (1983) as follows: suppose the system begins to operate at time 0 and that the time for repair is negligible. Let $T_0, T_1, T_2, \ldots$ ($T_0 = 0$) denote the system of failure times and let $X_i = T_i - T_{i-1}, i = 1, 2, \ldots$, denote, as above, the times between failures (the working times).

**Definition 3.1.2** Let $F(t) = P(X_1 \leq t), t \geq 0$. The system undergoes **minimal repairs** at failures if and only if

$$P\left( X_n < u \left| \sum_{i=1}^{n-1} X_i = t \right. \right) = \frac{F(t + u) - F(t)}{S(t)}, \quad n = 2, 3, \ldots$$

for $u > 0, t \geq 0$, such that $F(t) < 1$. $\Box$

Following Andersen et al. (1993, Section II.4) the **conditional intensity** $\lambda(t | \mathcal{F}_{t-})$ of a point process $\{N(t), t \geq 0\}$ is defined by

$$\gamma(t) := \lambda(t | \mathcal{F}_{t-}) = \lim_{\Delta t \downarrow 0} \frac{P(\text{failure in a point process in } [t, t + \Delta t] | \mathcal{F}_{t-})}{\Delta t}, \quad t > 0, \quad (3.1)$$

where $\mathcal{F}_{t-} = \sigma\{N(u), u < t\}$. Thus, $\gamma(t)\Delta t$ is approximately the probability of failure in the time interval $[t, t + \Delta t)$, conditional on the experienced failure history before time $t$.

For a $\triangleright$ renewal process (p. 35) with inter-arrival distribution $F$ it is well known that $\gamma(t) = \rho(t - T_{N(t-)}), \quad$ where $\rho$ is the hazard rate corresponding to the distribution $F$, and $t - T_{N(t-)}$ is the time since the last failure strictly before time $t$. Thus at each failure, the conditional intensity is returned to what it was at
time 0, which means that the system is as good as new immediately after each failure. This is a perfect repair model.

On the other hand, a $\triangleright$ non-homogeneous Poisson process (p. 36) with intensity function $\lambda(t)$ has the conditional intensity $\gamma(t) = \lambda(t)$. This means that the conditional intensity after a failure is exactly as if no failure had ever occurred. Thus at failures, the system is only restored to a condition where it is exactly as good (or bad) as it was immediately before the failure. This is a minimal repair model.

3.2 Models for repairable systems

In this section we recall the definitions of the most common point processes which are used to model repairable systems. The two point processes, non-homogeneous Poisson process $\{N(t), t \geq 0\}$ and renewal process $\{T_i, i = 1, 2, \ldots\}$, are widely investigated in the literature on reliability to model minimal repairs and perfect repairs (renewals). In Section 3.2.6, a wider class of processes, the class of so called trend-renewal processes, is described, which covers non-homogeneous Poisson and renewal processes.

3.2.1 Homogeneous Poisson process

Definition 3.2.3 The process $N(t), t \geq 0$ is said to be a (homogeneous) Poisson process with rate (or intensity) $\lambda > 0$ if

(i) $N(0) = 0$;

(ii) the number of events $N(s_2) - N(s_1)$ and $N(t_2) - N(t_1)$ in disjoint time intervals $(s_1, s_2]$ and $(t_1, t_2]$ are independent (independent increments);

(iii) the distribution of the number of events in a certain interval depends only on the length of the interval and not on its position (stationary increments);

(iv) $\lim_{\Delta t \to 0} \frac{P(N(\Delta t) = 1)}{\Delta t} = \lambda$;

(v) $\lim_{\Delta t \to 0} \frac{P(N(\Delta t) \geq 2)}{\Delta t} = 0$.

The process defined above will be denoted by HPP($\lambda$). Note that if the random variables $X_1, X_2, \ldots$ (waiting times) are independent and exponentially distributed $\mathcal{E}(1/\lambda)$, the counting process $\{N(t), t \geq 0\}$ is the HPP($\lambda$). The corresponding sequence $\{T_i, i = 1, 2, \ldots\}$ is also called the HPP($\lambda$).
Let us note that in the HPP($\lambda$) the number of events in an interval of length $t$ is a random variable having the Poisson distribution $P(\lambda t)$, and that the time of the $n$-th event is a random variable $G(n, 1/\lambda)$ distributed.

Major weakness of a HPP are the constant rate assumption and the fact that the distribution of the number of events in an interval depends only on the length of the interval and not on its position.

**Poisson process simulation**

To generate $n$ first successive event times of the HPP($\lambda$) one can use the fact that the inter-arrival times $X_i, i = 1, 2, \ldots$, are independent random variables having the exponential distribution $\mathcal{E}(1/\lambda)$. One of the simulation methods of the HPP($\lambda$) is then generating the inter-arrival times $X_i, i = 1, 2, \ldots$, according to the inversion method formula $X_i = -\frac{1}{\lambda} \ln U_i$, where $U_i$ are random numbers from the uniform distribution $\mathcal{U}(0, 1)$. Then

$$T_j = \sum_{i=1}^{j} X_i, \quad j = 1, \ldots, n,$$

are the successive $n$ event times of the HPP($\lambda$).

Let us note that to generate the event times on a given interval time $(0, t)$, the number of failures in this time interval is determined by the formula

$$\inf \left\{ n : \sum_{i=1}^{n} X_i > t \right\} - 1.$$

Thus in generating the HPP($\lambda$) in the interval $(0, t)$ one can use the following algorithm:

1: $s = 0, n = 0$;
2: generate the random number $U \sim \mathcal{U}(0, 1)$;
3: set $X = -\frac{1}{\lambda} \ln U$;
4: $s = s + X$; if $s > t$, then stop the procedure;
5: $n = n + 1, T_n = s$;
6: go to step 2.
The last value \( n \) in the algorithm above represents the number of failures in the process in the interval \((0, t]\), and \(T_1, \ldots, T_n\) are the successive \( n \) event times of the HPP(\(\lambda\)) in this time interval.

Generating the HPP(\(\lambda\)) until a given number of failures appears is conducted according to the following main formula:

\[
T_i = \left( T_{i-1} + \frac{1}{\lambda} \ln \frac{1}{1 - U_i} \right), \quad i = 1, 2, \ldots, \tag{3.2}
\]

\(T_0 = 0\), where \(U_i\) are random numbers from uniform distribution \(U(0, 1)\). The generating formula is equivalent to

\[
T_i = \left( T_{i-1} - \frac{1}{\lambda} \ln U_i \right), \quad i = 1, 2, \ldots,
\]

but for numerical computation reasons the first formula is more useful.

### 3.2.2 Renewal process

**Definition 3.2.4** The process \(\{N(t), t \geq 0\}\) is a **renewal process** if the random variables \(X_1, X_2, \ldots\) are independent and identically distributed with cumulative distribution function (cdf) \(F\) with \(F(0) = 0\).

The renewal process will be denoted by \(\text{RP}(F)\). The sequence \(\{T_i, i = 1, 2, \ldots\}\) is called the \(\text{RP}(F)\) too. If \(F\) is the cdf of the exponential distribution \(\mathcal{E}(\lambda)\), then \(\text{RP}(F)\) is HPP(\(\lambda\)).
3.2.3 Non-homogeneous Poisson process

Definition 3.2.5 A process \( \{N(t), t \geq 0\} \) is a non-homogeneous Poisson process with intensity function \( \lambda(t), t \geq 0 \), if

(i) \( N(t) = 0 \), i.e. there are no events at time 0;

(ii) the numbers of events \( N(s_2) - N(s_1) \) and \( N(t_2) - N(t_1) \) in disjoint intervals \( (s_1, s_2] \) and \( (t_1, t_2] \) are independent random variables (independent increments);

(iii) there exists a function \( \lambda(t) \) such that

\[
\lim_{\Delta t \to 0} \frac{P(N(t + \Delta t) - N(t) = 1)}{\Delta t} = \lambda(t);
\]

(iv) for each \( t > 0 \), \( \lim_{\Delta t \to 0} \frac{P(N(t + \Delta t) - N(t) \geq 2)}{\Delta t} = 0 \).

The process defined above will be denoted by \( \text{NHPP}(\lambda(\cdot)) \).

The important consequence of conditions (i)–(iv) is that the number of failures in the interval \( (s, t], t > s \), has the Poisson distribution with the parameter
\[ \int_s^t \lambda(u) \, du, \text{ i.e.,} \]
\[ P(N(t) - N(s) = k) = \frac{\left(\int_s^t \lambda(u) \, du\right)^k}{k!} \exp\left(-\int_s^t \lambda(u) \, du\right) \]

The functions \( \lambda(t) \) and \( \Lambda(t) = \int_0^t \lambda(u) \, du \) are called the **intensity function** and the **cumulative intensity function** of the process, respectively.

Of course, if \( \lambda(t) \equiv \lambda \), then the NHPP(\( \lambda(\cdot) \)) is the HPP(\( \lambda \)).

Note that the definition of a NHPP relaxes the stationarity assumption of a HPP.

**Fact 3.2.1** The process \( \{N(t), t \geq 0\} \) is an NHPP(\( \lambda(\cdot) \)) if the time-transformed process \( \Lambda(T_1), \Lambda(T_2), \ldots \) forms an HPP(1), i.e., if \( N(t) = \tilde{N}(\Lambda(t)) \), where \( \{\tilde{N}(t), t \geq 0\} \) is an HPP(1).

**Theorem 3.2.1** Suppose that events are occurring according to an HPP(\( \lambda \)). Suppose that, independently of anything that occurred before, an event that happens at time \( t \) is counted with probability \( p(t) \). Then the process \( \{N(t), t \geq 0\} \) of counted events constitutes an NHPP(\( \lambda p(\cdot) \)).

The mean value function of an NHPP(\( \lambda(\cdot) \)) is \( E(N(t)) = \Lambda(t) \). This function gives the mean (expected) number of failures up to time \( t \).

Let \( F_i \) denote the distribution function of the occurrence times \( T_i, i = 1, 2, \ldots \), and \( f_i \) be the density function. We have

\[ F_i(t) = P(T_i \leq t) = P(N(t) \geq i) = 1 - \sum_{k=1}^{i-1} P(N(t) = k) \]
\[ = 1 - \sum_{k=0}^{i-1} \left( \int_0^t \lambda(y) \, dy \right)^k \frac{1}{k!} e^{-\int_0^t \lambda(y) \, dy} = 1 - \sum_{k=0}^{i-1} \frac{[\Lambda(t)]^k}{k!} e^{-\Lambda(t)} \]

and

\[ f_i(t) = \frac{dF_i(t)}{dt} = -\sum_{k=0}^{i-1} \left( \frac{k [\Lambda(t)]^{k-1} \Lambda'(t) e^{-\Lambda(t)}}{k!} + \frac{[\Lambda(t)]^k}{k!} e^{-\Lambda(t)} (-\Lambda'(t)) \right) \]
\[ = \Lambda'(t) e^{-\Lambda(t)} \left( \frac{[\Lambda(t)]^i}{i!} \right) = \lambda(t) e^{-\Lambda(t)} \left( \frac{[\Lambda(t)]^{i-1}}{(i-1)!} \right). \]

If \( F_{\Lambda_i} \) denotes the distribution function of \( \Lambda(T_i) \), then

\[ F_{\Lambda_i}(t) = P(\Lambda(T_i) \leq t) = P(T_i \leq \Lambda^{-1}(t)) = 1 - \sum_{k=0}^{i-1} \frac{t^k}{k!} e^{-t}. \]
On the other hand,

\[ F_{\Lambda_i}(t) = P\left( \tilde{N}(t) \geq i \right) = \sum_{k=i}^{\infty} \frac{t^k}{k!} e^{-t} = \frac{1}{(i-1)!} \int_0^t u^{i-1} e^{-u} du. \]

It then follows that \( \Lambda(T_i) = \sum_{k=1}^{i} W_k, \ i = 1, 2, \ldots \), has the gamma distribution \( G(i, 1) \); \( W_k = \Lambda(T_k) - \Lambda(T_{k-1}) \), \( k = 1, 2, \ldots \), are exponentially distributed \( E(1) \) and that the transformed counting process \( \{ N(\Lambda(t)), t \geq 0 \} \) is the Poisson process with intensity 1, i.e., it is the HPP(1) as a special renewal process \( \text{RP}(1-\exp(-t)) \).

Special classes of NHPP’s which play important role in modeling reliability systems will be presented in the next two subsections.

**Simulation of a non-homogeneous Poisson process**

**A.** Random sampling or thinning approach. The procedure follows the following steps: 1) choose a \( \lambda(t) \) such that \( \lambda(t) \leq T \) for all \( t \leq T \); 2) generate events according to a HPP(\( \lambda \)); 3) accept the event, say at time \( t \), with probability \( \frac{\lambda(t)}{\lambda} \), independently of what has happened before. The process of the counted events then forms the NHPP(\( \lambda(t) \)), \( \lambda(t), t \leq T \).

The algorithm is:

1: \( t = 0, n = 0 \);
2: generate a random number \( U \sim U(0, 1) \);
3: set \( X = -\frac{1}{\lambda} \ln U \);
4: \( t = t + X \); If \( t > T \) then stop;
5: generate a random number \( U \sim U(0, 1) \);
6: if \( U \leq \frac{\lambda(t)}{\lambda} \), set \( n = n + 1, T_n = t \);
7: go to step 2.

In the output, \( n \) is the number of events in the time interval \( (0, T) \), and \( T_1, \ldots, T_n \) are the successive \( n \) event times of the NHPP(\( \lambda(t) \)) in this time interval.

**B.** The method of direct generation of successive event times \( T_i, \ i = 1, 2, \ldots \), relies on the Fact 3.2.1, i.e., on the formula \( \Lambda(T_i) - \Lambda(T_{i-1}) \sim E(1) \sim -\ln U_i \). This corresponds to the formula: \( T_i = \Lambda^{-1}(\Lambda(T_{i-1}) - \ln U_i) \).
3.2.4 Power law process (PLP)

**Definition 3.2.6** The NHPP($\lambda(\cdot)$) for which $\lambda(t) = \lambda(t; \alpha, \beta) = \alpha \beta t^{\beta - 1}, \alpha > 0, \beta > 0$, is called the **Power Law Process**.

This process will be denoted by PLP($\alpha, \beta$). This NHPP is also known as **Weibull NHPP**. The cumulative intensity function for this process is $\Lambda(t; \alpha, \beta) = \alpha t^\beta$.

Figures 3.2, 3.3 and 3.4 show the plots of the intensity functions $\lambda(t; \alpha, \beta)$, the cumulative intensity functions $\Lambda(t; \alpha, \beta)$ and the plots of trajectories of the PLP($\alpha, \beta$) for three chosen pairs of $\alpha$ and $\beta$. 

![Figure 3.2: Intensity functions $\lambda(t; \alpha, \beta)$ of the PLP($\alpha, \beta$) for three chosen pairs of $\alpha$ and $\beta.](image)
Figure 3.3: Cumulative intensity functions $\Lambda(t; \alpha, \beta)$ of the PLP$(\alpha, \beta)$ for three chosen pairs of $\alpha$ and $\beta$.

Figure 3.4: Sample paths of the PLP$(\alpha, \beta)$ for three chosen pairs of $\alpha$ and $\beta$. 
Figure 3.4 shows three sample paths of the PLP\((\alpha, \beta)\) for each of the three chosen combinations \((50,0.2),(15,2)\) and \((2,5)\) of the pair \((\alpha, \beta)\). The experimental average numbers of jumps evaluated from 100 generated repetitions of the PLP for the three chosen pairs of \(\alpha\) and \(\beta\) in the simulation are equal to 48, 61, 52, respectively (compare with the values of \(\hat{n}\) in Table 4.1 for \(T = 2\)).

**Simulation of a power law process**

Generating the PLP\((\alpha, \beta)\) process until a given number of jumps (failures) is based on the following formula:

\[
T_i = \left( T_{i-1}^\beta + \frac{1}{\alpha} \ln \frac{1}{1 - U_i} \right)^{1/\beta}, \quad i = 1, 2, \ldots, (3.3)
\]

\(T_0 = 0\), where \(U_i\) are random numbers from uniform distribution \(\mathcal{U}(0,1)\). The generating formula is equivalent to

\[
T_i = \left( T_{i-1}^\beta - \frac{1}{\alpha} \ln U_i \right)^{1/\beta}, \quad i = 1, 2, \ldots,
\]

but for numerical computation reasons the previous formula is more useful.

### 3.2.5 Non-homogeneous Poisson processes with bounded mean value function

Let \(\{N(t), t \geq 0\}\) be a NHPP with intensity function \(\lambda(t)\) and the mean value function \(\Lambda(t) = \int_0^t \lambda(u)du\) (cumulative intensity) having the following parametric form

\[
\Lambda(t; \alpha, \beta) = \alpha F(t/\beta), \quad (3.4)
\]

where \(\alpha, \beta > 0\) are unknown parameters, and \(F(\cdot)\) is a known continuous, differentiable distribution function. The corresponding intensity function is given by

\[
\lambda(t; \alpha, \beta) = \frac{\alpha}{\beta} f(t/\beta), \quad (3.5)
\]

where \(f(\cdot)\) is the differential coefficient of \(F(\cdot)\). It is obvious that the model defined by (3.4) has bounded mean value function. This is the reason for which this model is used as a software reliability model, because a software system contains only a finite number of faults. The parameter \(\alpha\) is called the expected number of faults to be eventually detected (see Yamada and Osaki (1985)) and \(\beta\) is a scale parameter.
3.2.6 Trend-renewal process (TRP)

The TRP was introduced and investigated first by Lindqvist (1993) and by Lindqvist et al. (1994) (see also Lindqvist and Doksum (2003)).

Let $\lambda(t)$ be a nonnegative function defined for $t \geq 0$, and let $\Lambda(t) = \int_0^t \lambda(u)du$.

**Definition 3.2.7** The process $\{N(t), t \geq 0\}$ is called a trend-renewal process TRP$(F, \lambda(\cdot))$ if the time-transformed process $\Lambda(T_1), \Lambda(T_2), \ldots$ is an RP$(F)$, i.e. if the random variables $\Lambda(T_i) - \Lambda(T_{i-1}), i = 1, 2, \ldots$ are i.i.d. with cdf $F$.

![Figure 3.5: The idea of the TRP model.](image)

The cdf $F$ is meant as the renewal distribution function, and $\lambda(t)$ is called the trend function.

Let us note that for $F(t) = 1 - \exp(-t)$ the TRP$(1 - \exp(-t), \lambda(\cdot))$ becomes the NHPP$(\lambda(\cdot))$. Let us also remark that in particular, the TRP$(F, 1)$ is the RP$(F)$.

The class of TRP’s is defined by properties of the sequence $\{T_i, i = 1, 2, \ldots\}$ and includes the NHPP’s and RP’s. Equivalently, the corresponding counting process $\{N(t), t \geq 0\}$ can be considered, where $N(t) = \tilde{N}(\Lambda(t))$ and $\{\tilde{N}(t), t \geq 0\}$ represents an RP.

Note that the representation TRP$(F, \lambda(\cdot))$ is not unique. For uniqueness we assume that the expected value of the renewal distribution defined by $F$ equals 1.

The form of conditional intensity function of the TRP$(F, \lambda(\cdot))$ one obtains
from formula (3.1). Namely, we have
\[
\gamma(t) = \lim_{\Delta t \to 0} \frac{P(\text{failure in TRP in } (t, t+\Delta t) | F_{t-})}{\Delta t} \\
= \lim_{\Delta t \to 0} \frac{P(\text{failure in RP}(F) in (\Lambda(t), \Lambda(t+\Delta t)) | F_{t-})}{\Delta \Lambda(t)} \\
= \lim_{\Delta t \to 0} \frac{P(\text{failure in RP}(F) in (\Lambda(t), \Lambda(t+\Delta t)) | F_{t-}) \Delta \Lambda(t)}{\Delta t}.
\]
The conditional intensity function of the RP(F) is given by
\[
\gamma(t) = \rho(t - T_{N(t-)}),
\]
where \(\rho(t)\) is the \(\triangleright\) hazard rate (p. 1) corresponding to \(F\). It then follows that for the TRP\((F, \lambda(\cdot))\) the conditional intensity function is
\[
\gamma(t) = \rho(\Lambda(t) - \Lambda(T_{N(t-)})) \lim_{\Delta t \to 0} \frac{\Lambda(t + \Delta t) - \Lambda(t)}{\Delta t} = \rho(\Lambda(t) - \Lambda(T_{N(t-)})) \lambda(t). \tag{3.6}
\]

### 3.2.7 Weibull-power law TRP

Let us consider the TRP\((F, \lambda(\cdot))\) with
\[
\lambda(t; \alpha, \beta) = \alpha \beta t^{\beta-1}, \quad \alpha > 0, \beta > 0, \quad \Lambda(t; \alpha, \beta) = \alpha t^\beta \tag{3.7}
\]
and
\[
F(x) = F(x; \gamma) = 1 - \exp \left[ - \left( \Gamma(1 + 1/\gamma)x \right)^\gamma \right] \quad (\gamma > 0), \tag{3.8}
\]
studied by Lindqvist et al. (2003). The renewal distribution function \(F\) corresponds to the Weibull distribution \(We(\gamma, 1/\Gamma(1+1/\gamma))\) with the parametrization resulting in the expectation 1.

**Definition 3.2.8** The TRP\((F, \lambda(\cdot))\) with \(\lambda(\cdot)\) and \(F\) defined by 3.7 and 3.8 is called the **Weibull-Power Law TRP**. \(\square\)

The Weibull-Power Law TRP will be denoted shortly by \(WPLP(\alpha, \beta, \gamma)\).

The hazard function corresponding to \(F\) is
\[
\rho(x) = \rho(x; \gamma) = (\Gamma(1 + 1/\gamma))^\gamma \gamma x^{\gamma-1}. \tag{3.9}
\]
In the case \(\gamma = 1\) the renewal distribution function \(F\) corresponds to the exponential distribution \(E(1)\) and the WPLP\((\alpha, \beta, 1)\) becomes the NHPP\((\lambda(t))\) with \(\lambda(t) = \alpha \beta t^{\beta-1}\), i.e., it becomes the PLP\((\alpha, \beta)\). Note that in this case \(\varphi = \alpha\).

If \(\gamma = 1\) and \(\beta = 1\), then the WPLP\((\alpha, 1, 1)\) is the TRP\((1 - \exp(-t), \alpha)\), i.e., it is the HPP\((\alpha)\).
Figure 3.6: Sample paths of the WPLP($\alpha, \beta, \gamma$) for three chosen triplets of $\alpha$, $\beta$ and $\gamma$.

Figure 3.6 shows three sample paths of the WPLP($\alpha, \beta, \gamma$) for each of the three chosen combinations ($50, 0.2, 3$), ($15, 2, 1.5$) and ($2, 5, 0.8$) of the triplet ($\alpha, \beta, \gamma$). The experimental average numbers of jumps evaluated from 100 generated repetitions of the WPLP for the three chosen triplets of $\alpha$, $\beta$ and $\gamma$ in the simulation are equal to 51, 50, 53, respectively (compare with the values of $\hat{n}$ in Table 4.1 for $T = 2$).

Denote by $s = s(\gamma)$ the variance of the renewal distribution defined by $F$. For the WPLP($\alpha, \beta, \gamma$) we then have

\[ s = s(\gamma) = \frac{\Gamma(1 + 2/\gamma)}{\Gamma^2(1 + 1/\gamma)} - 1. \]  \hspace{1cm} (3.10)

In particular, $s = 1$ for the PLP($\alpha, \beta$).
Figures 3.8 – 3.10 illustrate how variability of a WPLP is reflected by the variance of the renewal distribution. The variability of the process becomes evidently greater as the variance $s$ of the renewal distribution defined by $F$ decreases. The variance function $s(\gamma)$ is strictly decreasing for $\gamma > 0$ and increases rapidly for $\gamma < 1$ (see formula (3.10) and Figure 3.7).
Figure 3.8: Sample paths of the WPLP(15, 2, 3).

Figure 3.9: Sample paths of the WPLP(15, 2, 1).
It follows from formula (3.9) that the hazard function $\rho(x; \gamma)$ corresponding to $F$ of the WPLP is decreasing in $x$ for $\gamma < 1$ (belonging then to DFR class) and increasing in $x$ for $\gamma > 1$ (belonging then to IFR class). For $\gamma = 2$ it is the linear function $\rho(x; 2) = 1.5708x$, and for $\gamma = 1$ it is a constant function which equals 1 and corresponds to the exponential distribution $\mathcal{E}(1)$. 

Figure 3.10: Sample paths of the WPLP(15, 2, 0.5).
Simulation of a Weibull-power law TRP

The successive jump times $T_1, T_2, \ldots$ of the WPLP$(\alpha, \beta, \gamma)$ are generated according to the following formula:

$$T_i = \left[ T_{i-1}^\beta + \frac{1}{\alpha \Gamma(1 + 1/\gamma)} \left( \ln \frac{1}{1 - U_i} \right)^{1/\gamma} \right]^{1/\beta}, \quad i = 1, 2, \ldots, \quad (3.11)$$

$T_0 = 0$, where $U_i$ are random numbers from uniform distribution $\mathcal{U}(0,1)$. The generating formula is equivalent to

$$T_i = \left[ T_{i-1}^\beta - \frac{1}{\alpha \Gamma(1 + 1/\gamma)} (\ln U_i)^{1/\gamma} \right]^{1/\beta}, \quad i = 1, 2, \ldots,$$

but for numerical computation reasons formula (3.11) is more useful.
Chapter 4

Parameter Estimation in Non-homogeneous Poisson Process with Power Law Intensity Function

4.1 Likelihood function for stochastic processes

Let \( \{Y(s), s \geq 0\} \) be a stochastic process observed in the time interval \([0, t]\).
Suppose that for each \( t \) the distribution \( P_t^{\vartheta} \) of the process \( \{Y(s), s \geq 0\} \) observed up to time \( t \) is an element of a family of distributions \( \{P_t^{\vartheta}, \vartheta \in \Theta\} \). Assume that for some fixed \( \vartheta_0 \in \Theta \), all the measures \( P_t^{\vartheta}, \vartheta \in \Theta \), are absolutely continuous with respect to the measure \( P_t^{\vartheta_0} \). The corresponding density (the Radon-Nikodym derivative)

\[
L(t; \vartheta) = L(t, y(\cdot); \vartheta, \vartheta_0) = \frac{dP_t^{\vartheta}}{dP_t^{\vartheta_0}}(y(\cdot))
\]

regarded as a function of \( \vartheta \) given the data (realization) \( y(\cdot) \) is called the likelihood function of the process \( \{Y(s), s \geq 0\} \) observed in the time interval \([0, t]\).

In the discrete time process \( \{Y(s), s = 0, 1, 2, \ldots\} \) the likelihood function always exists if the distributions \( P_t^{\vartheta}, P_t^{\vartheta_0} \) have positive densities, and it coincides with the ratio of these two densities.

The likelihood function can be often calculated using the limit relation

\[
L(t; \vartheta) = \lim_{n \to \infty} \frac{p_{\vartheta}(y(t_1), \ldots, y(t_n))}{p_{\vartheta_0}(y(t_1), \ldots, y(t_n))},
\]
where \( p_0 \) denotes the density of the vector \((y(t_1), \ldots, y(t_n))\), while \( \{t_1, \ldots, t_n\} \) is a dense set in \([0, t]\).

Note that by the fundamental identity of sequential analysis for stochastic processes, which is a consequence of the optional stopping theorem, the form of the likelihood function of (4.1) remains the same, where the end time \( t \) is replaced with a random finite stopping time \( \tau \) with respect to the family \( \mathcal{F}_t = \sigma\{Y(s), s \leq t\}, t \geq 0 \).

If \( \{Y_0, Y_1, Y_2, \ldots\} \) forms a homogeneous Markov chain, then under quite general assumptions the likelihood function is

\[
\frac{dP_t}{dP_0}(y(\cdot)) = p_0(Y_0; \vartheta)p(Y_1|Y_0; \vartheta) \cdots p(Y_t|Y_{t-1}; \vartheta),
\]

where \( p_0 \) and \( p \) are the initial and transition densities of the distribution.

Let \( \{Y(s), s \geq 0\} \) be a homogeneous Markov process with a discrete state space and differentiable transition probabilities \( p_{i,j}(s) \). The transition probability matrix is determined by the matrix \( Q = (q_{i,j}) \), where \( q_{i,j} = p'_{i,j}(0) \). Denote \( q_i = -q_{i,i} \) and let \( y_0 = i_0 \) be independent of \( Q \) at the initial time. By choosing any matrix \( Q_0 = (q^0_{i,j}) \), one finds

\[
\frac{dP_t}{dP_0^Q}(y(\cdot)) = \exp \left[ (q^0_{(0)}) - q_{(0)}(t_N) \right] \sum_{k=0}^{N(t)-1} \frac{q_{y(t_N),y(t_{k+1})}}{q_{y(t_N),y(t_k)}} \cdot \exp \left[ x_k(q_{y(t_N)} - q_{y(t_k)} - q^0_{y(t_k)} + q^0_{y(t_N)}) \right],
\]

where \( N(t) \) is the number of jumps of the process \( \{Y(s), s \geq 0\} \) in the interval \([0, t] \); \( t_k \) is the \( k \)-th jump time; \( x_k = t_{k+1} - t_k \) is the inter-arrival time. The ML estimators of the parameters \( q_{i,j} \) are \( \hat{q}_{i,j} = \frac{K_{i,j}(t)}{S_i} \), where \( K_{i,j}(t) \) is the number of transitions from state \( i \) to state \( j \) in the time interval \([0, t] \), and \( S_i(t) \) is the time spent in state \( i \) before \( t \).

Let \( \{Y(s), s \geq 0\} \) be the linear birth-and-death process with birth rate \( \lambda > 0 \) and death rate \( \mu > 0 \). The counting process \( N(t) \) in this model is the number of births and deaths in the time interval \([0, t] \). For the process \( Y \) we have \( q_{i,i+1} = i\lambda, q_{i,i-1} = i\mu, q_{i,i} = 1 - i(\lambda + \mu) \) and \( q_{i,j} = 0 \) if \( |i - j| > 1 \). Assume that \( Y(0) = 1 \).
The likelihood function is

\[ L((\lambda, \mu); t) = \frac{dP_{(\lambda, \mu)}^t(y(\cdot))}{dP_{(\lambda_0, \mu_0)}^t(y(\cdot))} = \left( \frac{\lambda}{\lambda_0} \right)^{B(t)} \left( \frac{\mu}{\mu_0} \right)^D(t) \exp \left[ -(\lambda + \mu - \lambda_0 - \mu_0)S(t) \right] \]

\[ = \exp \left[ \vartheta_1 B(t) + \vartheta_2 D(t) - \left( e^{\vartheta_1} + e^{\vartheta_2} \right) S(t) \right] =: L(\vartheta; t), \]

where \( \vartheta = (\vartheta_1, \vartheta_2) = (\log \lambda, \log \mu) \). \( B(t) \) is the number of births (jumps of measure +1) in \([0, t]\), \( D(t) \) is the number of deaths (jumps of measure -1) in \([0, t]\), and

\[ S(t) = \int_0^t y(s)ds \]

is the total time lived in the population before time \( t \). The ML estimators of \( \lambda \) and \( \mu \) are

\[ \hat{\lambda}(t) = \frac{B(t)}{S(t)}, \quad \hat{\mu}(t) = \frac{D(t)}{S(t)} \]

If \( \{N(s), s \geq 0\} \) is the HPP(\( \lambda \)), then the likelihood function is

\[ L(\lambda; t) = \lambda^{N(t)} \exp(-\lambda t) = \exp \left[ \vartheta N(t) - e^\vartheta t \right] =: L(\vartheta; t), \]

where \( \vartheta = \log \lambda \). The ML estimator of \( \lambda \) is \( \hat{\lambda} = \frac{N(t)}{t} \).

### 4.2 Maximum likelihood estimators in a PLP

Let \( \{N(t), t \geq 0\} \) be a NHPP with a mean value function \( \Lambda(t; \vartheta) \) and intensity function \( \lambda(t; \vartheta) \), where \( \vartheta \) is an unknown vector parameter. For this process observed on the time interval \([0, \tau]\), the likelihood function based on the observed arrival times \( t_1, t_2, \ldots, t_{N(\tau)} \) and \( N(\tau) \) is of the form

\[ L(\tau; \vartheta) = L(t_1, t_2, \ldots, t_{N(\tau)}, N(\tau); \vartheta) = \left[ \prod_{i=1}^{N(\tau)} \lambda(t_i; \vartheta) \right] \exp \left[ -\Lambda(\tau; \vartheta) \right], \quad (4.2) \]

dropping the factor which does not depend on an unknown parameter. The form of the likelihood function follows from the formula given by Andersen et al. (1993)
for the likelihood function of a point process (see also Thompson (1988)). That
likelihood function of a point process is used in the next section. Formula (4.2) one
obtains from formula (5.1) by assuming that the conditional intensity \( \gamma(t) = \lambda(t) \).

In particular, for the PLP(\( \alpha, \beta \)) the **likelihood function** defined by (4.2)
takes the form

\[
L(\tau; \alpha, \beta) = (\alpha \beta)^{N(\tau)} \prod_{i=1}^{N(\tau)} t_i^{\beta-1} \exp\left(-\alpha \tau^\beta \right)
\]

For the PLP(\( \alpha, \beta \)) the ML estimators of \( \alpha \) and \( \beta \) can be explicitly determined
(see e.g. Rigdon and Basu (2000), pp. 136–137).

The **log-likelihood function** for the PLP(\( \alpha, \beta \)) is

\[
\ell(\tau; \vartheta) := \log L(\tau; \vartheta) = \log L(\tau; \alpha, \beta)
= N(\tau)(\ln \alpha + \ln \beta) + (\beta - 1) \sum_{i=1}^{N(\tau)} \ln t_i - \alpha \tau^\beta.
\]

Solving the **likelihood equations**

\[
\begin{cases}
\frac{\partial \ell(\tau; \alpha, \beta)}{\partial \alpha} = 0, \\
\frac{\partial \ell(\tau; \alpha, \beta)}{\partial \beta} = 0.
\end{cases}
\tag{4.3}
\]

we obtain the form of the ML estimators given in the following fact:

**Fact 4.2.1** For the PLP(\( \alpha, \beta \)) the **ML estimators** \( \hat{\alpha}_{ML} \) and \( \hat{\beta}_{ML} \) of \( \alpha \) and \( \beta \), based on the observation up to any stopping time \( \tau \), are of the form

\[
\hat{\alpha}_{ML} = \frac{N(\tau)}{\tau^{\beta_{ML}}}
\tag{4.4}
\]

and

\[
\hat{\beta}_{ML} = N(\tau) \left( \frac{\ln \tau^{N(\tau)}}{\prod_{i=1}^{N(\tau)} t_i} \right)^{-1} = N(\tau) \left( \sum_{i=1}^{N(\tau)} \frac{\ln t_i}{T_i} \right)^{-1}.
\tag{4.5}
\]

In the case when the observation is finished at the \( n \)-th failure time point, i.e.,
\( \tau = T_N(\tau) \) and \( N(\tau) = n \), in other words if the observation time is the random
stopping time \( \tau = \inf\{t \geq 0; N(t) = n\} \), then we say that the stopping time \( \tau \)
determines the so called **inverse estimation plan**. This way of terminating
the observation of the process, as soon as a predetermined number of failures has been observed, is called **failure truncation**.

In the case when the observation is finished at a predetermined time, say \( T \), i.e., \( \tau = \text{const} = T \), then we say that the stopping time \( \tau \) determines the so-called **simple estimation plan**. This way of terminating the observation of the process is called **time truncation**.

**Fact 4.2.2** In the inverse estimation plan for the \( \text{PLP}(\alpha, \beta) \) the ML estimators of \( \alpha \) and \( \beta \) are defined by

\[
\hat{\alpha}_{\text{ML}} = \frac{n}{T_n^{\beta_{\text{ML}}}}, \quad \text{where} \quad \hat{\beta}_{\text{ML}}^I = n \left( \ln \frac{T_n}{\prod_{i=1}^{n} T_i} \right)^{-1} = n \left( \sum_{i=1}^{n-1} \ln \frac{T_n}{T_i} \right)^{-1}. \tag{4.6}
\]

In the simple estimation plan for the \( \text{PLP}(\alpha, \beta) \) the ML estimators of \( \alpha \) and \( \beta \) are defined by

\[
\hat{\alpha}_{\text{ML}}^S = \frac{N(T)}{T^{\beta_{\text{ML}}^S}}, \tag{4.7}
\]

where

\[
\hat{\beta}_{\text{ML}}^S = N(T) \left( \ln \frac{T_n^{N(T)}}{\prod_{i=1}^{N(T)} T_i} \right)^{-1} = N(T) \left( \sum_{i=1}^{N(T)} \ln \frac{T_n}{T_i} \right)^{-1}. \tag{4.8}
\]

For the \( \text{HPP}(\alpha) \) the ML estimator of \( \alpha \) in the inverse estimation plan is

\[
\hat{\alpha}_{\text{ML}}^I = \frac{n}{T_n}, \tag{4.9}
\]

and in the simple estimation plan is

\[
\hat{\alpha}_{\text{ML}}^S = \frac{N(T)}{T}. \tag{4.10}
\]

Let us note that in the simple estimation plan for a PLP the ML estimators depend on \( N(T) \), the number of failures up to time \( T \), and on the failure times \( T_i, i = 1, \ldots, N(T); 0 < T_1 < T_2 < \cdots < T_{N(T)} \leq T \). Remark that the number \( N(T) \) as well as the failure times \( T_i \) are random, whereas in the inverse estimation plan the ML estimators are determined only by \( T_1, \ldots, T_n \), where \( n \) is the number of failures given at advance.
4.3 Expected number of failures

The expected number of failures in the PLP($\alpha, \beta$) up to time $T$ can be estimated by the formula $E(N(T)) = \hat{\alpha}T^{\hat{\beta}}$, where $\hat{\alpha}$ and $\hat{\beta}$ are estimates of the parameters $\alpha$ and $\beta$.

Table 4.1 contains estimates of $\alpha$ for given values of $\beta$ and the expected number of failures $\hat{n}$ at the termination time $T$ for the PLP($\alpha, \beta$). The estimates $\hat{\alpha}$ of the parameter $\alpha$ are evaluated according to the formula $\hat{n} = \Lambda(T; \hat{\alpha}, \hat{\beta}) = \hat{\alpha}T^{\hat{\beta}}$.

Chapter 5

Estimation of Parameters for Trend-renewal Processes

5.1 Introduction

In this chapter, methods of estimating unknown parameters of a trend function for trend-renewal processes (TRP’s) are investigated in the case when the renewal distribution function \( F \) is unknown. If the renewal distribution is unknown, then the likelihood function of the trend-renewal process is unknown and consequently the maximum likelihood method cannot be used. In such situation, three other methods of estimating the trend parameters are presented. The methods considered can also be used to predict future occurrence times. The performance of the estimators based on these methods is illustrated numerically for some TRP’s for which the statistical inference is analytically intractable.

Parametric inference on the parameters of the TRP was considered in the paper of Lindqvist et al. (2003), where the authors also proposed corresponding models, called heterogeneous TRP’s, that extend the TRP to cases involving unobserved heterogeneity. Nonparametric ML estimation of the trend function of a TRP\((F, \lambda(\cdot))\) under the often natural condition that \( \lambda(\cdot) \) is monotone was considered by Heggland and Lindqvist (2007).

Peña and Hollander (2004) presented a general class of models that allows the researcher to incorporate the effect of interventions performed on a unit after each event occurrence, the impact of accumulating events on a unit, the effect of unobservable random effects of frailties, and the effect of covariates that could be time-dependent. The ML estimators of this general models parameters were presented, and their finite and asymptotic properties were ascertained by Stocker and Peña (2007).
From practical point of view, the problem of estimating trend parameters of the TRP with unknown renewal distribution may be of interest in the situation when we observe several systems, of the same kind, working in different environments and we are interesting in examining and comparing their trend functions, whatsoever their renewal distribution is.

In Section 5.2 the form of likelihood function for a TRP is presented. The likelihood function and the likelihood equations for estimating the parameters of the Weibull-Power Law TRP are given in Section 5.3. The likelihood equations are also presented in the form which is used in simulation study to obtain the ML estimators of the TRP parameters. In Section 5.4, three methods of estimating the trend parameters in the case when the ML methods can not be used. The estimation problem of the trend parameters in some special case of the TRP is considered in Section 5.5. In Section 5.6 the estimators proposed are examined and compared with the ML estimators (obtained under the additional assumption that the renewal distribution has a known parametric form) through a computer simulation study. Some real data are examined in Section 5.6.3. Section 5.7 contains conclusions and some prospects.

5.2 Likelihood function for a TRP

For a point process $N(t)$ observed in the interval time $[0, \tau]$ with the realizations $t_1, t_2, \ldots, t_{N(\tau)}$ of the jump (failure) times $T_1, T_2, \ldots, T_{N(\tau)}$ and conditional intensity function $\gamma(t)$, the likelihood function is of the form

$$L(\tau) = \left[ \prod_{i=1}^{N(\tau)} \gamma(t_i) \right] \exp \left( - \int_0^\tau \gamma(u) du \right)$$

(5.1)

(Andersen et al. (1993)). The conditional intensity function $\gamma(t)$ is defined by (3.1).

Taking into account formula (3.6), the likelihood function of (5.1) takes the following form for the TRP($F, \lambda(\cdot)$):

$$L(\tau) = \left[ \prod_{i=1}^{N(\tau)} \rho(\Lambda(t_i) - \Lambda(t_{i-1})) \lambda(t_i) \cdot \exp \left( - \int_{t_{i-1}}^{t_i} \rho(\Lambda(u) - \Lambda(t_{i-1})) \lambda(u) du \right) \right]$$

$$\cdot \exp \left( - \int_{t_{N(\tau)}}^{\tau} \rho(\Lambda(u) - \Lambda(t_{N(\tau)})) \lambda(u) du \right).$$

Consequently, for a TRP($F, \lambda(\cdot)$) observed in the time interval $[0, \tau]$, by applying
the substitution \( v = \Lambda(u) - \Lambda(T_{i-1}) \), the **likelihood function** takes the form

\[
L(\tau) = \left[ \prod_{i=1}^{N(\tau)} z(\Lambda(t_i) - \Lambda(t_{i-1})) \lambda(t_i) \exp \left( - \int_0^{\Lambda(t_i) - \Lambda(t_{i-1})} \rho(v) dv \right) \right] \\
\cdot \exp \left( - \int_0^{\Lambda(\tau) - \Lambda(t_{N(\tau)})} \rho(v) dv \right)
\]

(5.2)

(Linqvist et al. (2003, formula (2, ch.2)) and the **log-likelihood function** is defined by

\[
\ell(\tau) := \log L(\tau)
= \sum_{i=1}^{N(\tau)} \left[ \log (\rho(\Lambda(t_i) - \Lambda(t_{i-1}))) + \log (\lambda(t_i)) - \int_0^{\Lambda(t_i) - \Lambda(t_{i-1})} \rho(v) dv \right] \\
- \int_0^{\Lambda(\tau) - \Lambda(t_{N(\tau)})} \rho(v) dv.
\]

(5.3)

### 5.3 Estimation in the Weibull-Power Law TRP

#### 5.3.1 Likelihood function

For the WPLP(\(\alpha, \beta, \gamma\)) the **likelihood function** defined by (5.2) takes the form

\[
L(\tau) = L(\tau; \vartheta) = \prod_{i=1}^{N(\tau)} \varphi \beta \gamma t_i^{\beta-1}(t_i^{\beta} - t_{i-1}^{\beta})^{\gamma-1} \\
\exp \left[ - \sum_{i=1}^{N(\tau)} \varphi(t_i^{\beta} - t_{i-1}^{\beta})^{\gamma} - \varphi(\vartheta^{\beta} - t_{N(\tau)}^{\beta})^{\gamma} \right],
\]

where \( \vartheta = (\varphi, \beta, \gamma) \) and

\[
\varphi = \varphi(\alpha, \gamma) = [\alpha \Gamma(1 + 1/\gamma)]^{\gamma}.
\]

(5.4)

The **log-likelihood function** for the WPLP(\(\alpha, \beta, \gamma\)) is

\[
\ell(\tau; \vartheta) := \log L(\tau; \vartheta)
= N(\tau) (\ln \varphi + \ln \beta + \ln \gamma) + (\beta - 1) \sum_{i=1}^{N(\tau)} \ln t_i + (\gamma - 1) \sum_{i=1}^{N(\tau)} \ln(t_i^{\beta} - t_{i-1}^{\beta}) \\
- \varphi \left[ \sum_{i=1}^{N(\tau)} (t_i^{\beta} - t_{i-1}^{\beta})^{\gamma} + (\vartheta^{\beta} - t_{N(\tau)}^{\beta})^{\gamma} \right].
\]
In the inverse estimation plan the likelihood function is given by
\[ \tilde{L}(n; \vartheta) = (\varphi \beta \gamma)^n \prod_{i=1}^{n} \left[ \left( t_i^\beta - t_{i-1}^\beta \right) \gamma \right] \exp \left\{ -\varphi \sum_{i=1}^{n} \left[ t_i^\beta - t_{i-1}^\beta \right] \right\}, \]
and the log-likelihood function is
\[ \tilde{\ell}(n; \vartheta) = n(\ln \varphi + \ln \beta + \ln \gamma) + n \sum_{i=1}^{n} \left[ (\beta - 1) \ln t_i + (\gamma - 1) \ln(t_i^\beta - t_{i-1}^\beta) - \varphi \left[ t_i^\beta - t_{i-1}^\beta \right] \right]. \]

5.3.2 ML estimators
The solution to the equation \( \partial \ell / \partial \varphi = 0 \) with respect to \( \varphi \) is
\[ \tilde{\varphi} = \tilde{\varphi}(\beta, \gamma) = \frac{N(\tau)}{\sum_{i=1}^{N(\tau)} \left( t_i^\beta - t_{i-1}^\beta \right) \gamma + (\tau^\beta - t_{N(\tau)}^\beta \gamma \gamma)} \tag{5.5} \]
Performing the likelihood equations for the parameters \( \beta \) and \( \gamma \) we have the following fact.

Fact 5.3.1 The ML estimators \( \hat{\varphi}_{ML}, \hat{\beta}_{ML} \) and \( \hat{\gamma}_{ML} \) of the parameters \( \varphi, \beta \) and \( \gamma \), based on the observation up to any stopping time \( \tau \), are determined as follows:
\[ \hat{\varphi}_{ML} = \frac{N(\tau)}{\sum_{i=1}^{N(\tau)} \left( t_i^\beta - t_{i-1}^\beta \right) \gamma + (\tau^\beta - t_{N(\tau)}^\beta \gamma \gamma)}, \]
where \( \hat{\beta}_{ML} \) and \( \hat{\gamma}_{ML} \) are the solutions of the following system of likelihood equations
\[ \frac{N(\tau)}{\beta} + \sum_{i=1}^{N(\tau)} \left\{ \left( t_i^\beta \ln t_i - t_{i-1}^\beta \ln t_{i-1} \right) \left[ \frac{\gamma - 1}{t_i^\beta - t_{i-1}^\beta} - \hat{\varphi} \gamma (t_i^\beta - t_{i-1}^\beta) \right] + \ln t_i \right\} - \hat{\varphi} \gamma (\tau^\beta - t_{N(\tau)}^\beta \gamma \gamma) \gamma = 0, \]
\[ \frac{N(\tau)}{\gamma} + \sum_{i=1}^{N(\tau)} \ln(t_i^\beta - t_{i-1}^\beta) [1 - \hat{\varphi}(t_i^\beta - t_{i-1}^\beta)] - \hat{\varphi} (\tau^\beta - t_{N(\tau)}^\beta \gamma) \ln (\tau^\beta - t_{N(\tau)}^\beta \gamma) = 0, \]
where \( \hat{\varphi} = \hat{\varphi}(\beta, \gamma) \) is defined by (5.5).

In particular, for the WPLP(\( \alpha, \beta, 1 \)), i.e. for the PLP(\( \alpha, \beta \)), we obtain the explicit form of the ML estimators of \( \alpha \) and \( \beta \), which are given in Fact 4.2.1 (formulae (4.4) and (4.5)).
In the inverse sequential estimation plan, the solution to the equation \( \partial \tilde{\ell} / \partial \varphi = 0 \) with respect to \( \varphi \) is

\[
\tilde{\varphi} = \tilde{\varphi}(\beta, \gamma) = \frac{n}{\sum_{i=1}^{n}(t_i^\beta - t_{i-1}^\beta)^\gamma},
\]  

and we have the following special case of Fact 5.3.1.

**Fact 5.3.2** The ML estimators \( \hat{\varphi}_{ML}, \hat{\beta}_{ML} \) and \( \hat{\gamma}_{ML} \) of the parameters \( \varphi, \beta \) and \( \gamma \) in the inverse estimation plan are determined as follows:

\[
\hat{\varphi}_{ML} = \frac{n}{\sum_{i=1}^{n}(t_i^{\beta_{ML}} - t_{i-1}^{\beta_{ML}})^{\gamma_{ML}}},
\]

where \( \hat{\beta}_{ML} \) and \( \hat{\gamma}_{ML} \) are the solutions of the following system of likelihood equations

\[
\begin{align*}
\frac{n}{\beta} + \sum_{i=1}^{n} \left[ t_i^\beta \ln t_i - t_i^\beta \ln t_{i-1} \right] \left[ \frac{\gamma - 1}{t_i^\beta - t_{i-1}^\beta} - \frac{\tilde{\varphi}(t_i^\beta - t_{i-1}^\beta)\gamma - 1}{t_i^\beta - t_{i-1}^\beta} \right] + \ln t_i &= 0, \\
\frac{n}{\gamma} + \sum_{i=1}^{n} \ln(t_i^\beta - t_{i-1}^\beta) \left[ 1 - \tilde{\varphi}(t_i^\beta - t_{i-1}^\beta)\gamma \right] &= 0,
\end{align*}
\]

where \( \tilde{\varphi} = \tilde{\varphi}(\beta, \gamma) \) is defined by (5.6).

The estimator \( \hat{\alpha} \) of \( \alpha \) is evaluated according to the formula

\[
\hat{\alpha} = \frac{\tilde{\varphi}^{1/\hat{\gamma}}}{\Gamma(1 + 1/\hat{\gamma})},
\]

where \( \tilde{\varphi} \) and \( \hat{\gamma} \) are estimators of \( \varphi \) and \( \gamma \).

Regarding that \( t_0 = 0 \), to avoid indeterminate expressions \((0 \cdot -\infty)\) in the numerical evaluations we express the formula for the log-likelihood function in the following form

\[
\tilde{\ell}(n; \vartheta) = n(\ln \varphi + \ln \beta + \ln \gamma) + (\beta - 1) \ln t_1 + (\gamma - 1) \ln t_1^\beta - \varphi t_1^{\beta \gamma}
+ \sum_{i=2}^{n} \left[ (\beta - 1) \ln t_i + (\gamma - 1) \ln(t_i^\beta - t_{i-1}^\beta) - \varphi(t_i^\beta - t_{i-1}^\beta)^\gamma \right].
\]

(5.10)

The derivative \( \partial \tilde{\ell} / \partial \beta \) is

\[
\begin{align*}
\frac{\partial \tilde{\ell}}{\partial \beta} &= \frac{n}{\beta} + \gamma(1 - \varphi t_1^{\beta \gamma}) \ln t_1 \\
&+ \sum_{i=2}^{n} \left[ t_i^\beta \ln t_i - t_i^\beta \ln t_{i-1} \right] \left[ \frac{\gamma - 1}{t_i^\beta - t_{i-1}^\beta} - \frac{\varphi(t_i^\beta - t_{i-1}^\beta)\gamma - 1}{t_i^\beta - t_{i-1}^\beta} \right] + \ln t_i \\
&+ \sum_{i=2}^{n} \left[ t_i^\beta \ln t_i - t_i^\beta \ln t_{i-1} \right] \left( \frac{\gamma - 1}{t_i^\beta - t_{i-1}^\beta} - \frac{\varphi(t_i^\beta - t_{i-1}^\beta)\gamma - 1}{t_i^\beta - t_{i-1}^\beta} \right) + \ln t_i.
\end{align*}
\]
and in the numerical computation we use the likelihood equation

\[ \frac{n}{\beta} + \gamma \left( 1 - \varphi(\beta, \gamma) t_1^{\beta \gamma} \right) \ln t_1 \]
\[ + \sum_{i=2}^{n} \left\{ \left[ t_i^{\beta} \ln t_i - t_{i-1}^{\beta} \ln t_{i-1} \right] - \frac{\gamma - 1}{t_i^{\beta} - t_{i-1}^{\beta}} - \varphi(\beta, \gamma) \gamma (t_i^{\beta} - t_{i-1}^{\beta})^{-1} \right\} + \ln t_i \right\} = 0 \]

instead of equation (5.8).

5.4 The alternative methods of estimating trend parameters of a TRP

In the case when both the form of the renewal distribution function \( F \) and the form of the trend function \( \lambda(\cdot) \) of the TRP\((F, \lambda(\cdot))\) are known one can estimate unknown parameters of this process using the maximum likelihood (ML) method. The problem is to find the estimators of unknown parameters of \( F \) and \( \lambda \) for which the likelihood function defined by (5.2) or the log-likelihood defined by (5.3) takes its maximum.

In the case when the form of \( F \) is unknown, we present in Sections 5.4.1, 5.4.2 and 5.4.3 the three methods for estimating unknown parameters of the trend function of a TRP\((F, \lambda(\cdot))\), where \( \lambda(\cdot) = \lambda(t; \vartheta) \) and \( \vartheta \) is a vector of unknown parameters. The problem of estimating trend parameters of the TRP with unknown renewal distribution may be of interest in the situation when we observe several systems, of the same kind, working in different environments and we are interesting in examining and comparing their trend functions, whatsoever their renewal distribution is. Moreover, the following limit results for the TRP hold

\[ \frac{N(t)}{\Lambda(t)} \rightarrow 1, \ a.s., \quad \frac{V(t)}{\Lambda(t)} \rightarrow 1 \ as \ t \rightarrow \infty, \]

where \( V(t) = E(N(t)) \) (see Lindqvist et al. (2003)). For NHPP\((\lambda(t))\) the equality \( V(t) = \Lambda(t) \) holds for every \( t \). Thus we may, at least asymptotically, think of \( \Lambda(t) \) as the expected number of failures until time \( t \). Therefore, we can use \( \hat{\Lambda}(t_0) = \Lambda(t_0; \hat{\vartheta}) \) as an estimator of \( V(t_0) \), for some \( t_0 \) large enough, whatsoever renewal distribution of the TRP is.
5.4.1 The least squares (LS) method

The least squares (LS) method consists in determining the value of $\hat{\vartheta}_{LS}$ that minimizes the quantity

$$S^2_{LS}(\vartheta) = \sum_{i=1}^{N(\tau)} [\Lambda(t_i; \vartheta) - \Lambda(t_{i-1}; \vartheta) - 1]^2,$$  \hspace{1cm} (5.11)

where $t_i$ are the realizations of random variables $T_i, i = 1, \ldots, N(\tau)$, and $\Lambda(t_0) := 0$. Let us note that the transformed inter-arrival times

$$W_i = \Lambda(T_i) - \Lambda(T_{i-1})$$

are the observations from the distribution with the expected value 1 (this is assumed for the uniqueness of the representation of a TRP). Thus the LS method consists in deriving such estimate of the unknown parameter $\vartheta$ (of the trend function) which minimizes the sum of squares of deviations of the random variables $W_i$ from the expected value 1 (i.e. minimizes the sample variance).

5.4.2 The constrained least squares (CLS) method

The constrained least squares (CLS) method consists in determining the value of $\vartheta$ that minimizes the quantity $S^2_{LS}(\vartheta)$ defined by (5.11) subject to the constraint

$$\frac{1}{N(\tau)} \sum_{i=1}^{N(\tau)} [\Lambda(t_i; \vartheta) - \Lambda(t_{i-1}; \vartheta)] = 1,$$

i.e., under the condition

$$\Lambda(t_{N(\tau)}; \vartheta) = N(\tau).$$  \hspace{1cm} (5.12)

Thus in the CLS method we assume additionally that the sample mean

$$\overline{W} = \frac{1}{N(\tau)} \sum_{i=1}^{N(\tau)} W_i$$

is equal to the theoretical expected value 1 of the distribution defined by $F$. 

5.4.3 The method of moments (M)

If the value of the variance of the renewal distribution $F$ is known, say $s$, then we can state the following condition on the sample variance:

$$\frac{1}{N(\tau) - 1} \sum_{i=1}^{N(\tau)} [\Lambda(t_i; \vartheta) - \Lambda(t_{i-1}; \vartheta) - 1]^2 = s.$$  

Taking into account (5.12) we have the following first two sample moment conditions:

$$\begin{align*}
\Lambda(t_{N(\tau)}/\vartheta) &= N(\tau), \\
\sum_{i=1}^{N(\tau)} [\Lambda(t_i; \vartheta) - \Lambda(t_{i-1}; \vartheta)]^2 &= (s + 1)N(\tau) - s. 
\end{align*}$$  

(5.13)

If $\vartheta = (\vartheta_1, \vartheta_2)$, then the method of moments (M method) consists in determining any solution $\hat{\vartheta}_M$ to the system of equations (5.13).

5.4.4 Some remarks

**Remark 5.4.1** The LS, CLS and M methods can be useful when we do not know the form of the cumulative distribution function $F$ (the renewal distribution), and consequently, when we do not know the likelihood function of the TRP $(F, \lambda(\cdot)).$

**Remark 5.4.2** The LS, CLS and M methods can be used to predict the next failure time. For example, we have $\hat{T}_{N(\tau)+1} = \hat{\Lambda}^{-1}[\hat{\Lambda}(T_{N(\tau)}) + 1]$, where $\hat{\Lambda}(t) = \Lambda(t; \hat{\vartheta}).$

**Remark 5.4.3** The LS, CLS and M methods can be the alternative methods of obtaining the estimators of an unknown parameter $\vartheta$ in the case when the maximum likelihood estimator does not exist. For example, in the case of $k$-stage Erlangian NHPP, which was first mentioned in Khoshgoftaar (1988), the maximum likelihood estimator exists and is unique if and only if some condition concerning the realizations of the process is satisfied (see Zhao and Xie (1996), Theorem 2.1 (ii)).

**Remark 5.4.4** In the NHPP models for which the number of failures is bounded there are no consistent estimators of the unknown parameters (see Nayak et al. (2008), Theorem 1). Thus, in these cases of the TRP, the estimators obtained by the ML, LS, CLS or M method are not consistent.
5.5 Estimation of trend parameters in special models of the TRP

Consider a TRP \((F, \lambda(t))\), where \(\lambda(t) = \alpha \beta t^{\beta-1}, \alpha > 0, \beta > 0\). If the renewal distribution function \(F\) is not specified, we will call this process the **Power Law TRP** \((F, \lambda(t))\) and denote it by \(\text{PTRP}(\alpha, \beta)\).

### 5.5.1 The LS method

Using the LS method we denote

\[
S_{LS}^2(\alpha, \beta) = \sum_{i=1}^{N(\tau)} \left[ \Lambda(t_i; \alpha, \beta) - \Lambda(t_{i-1}; \alpha, \beta) - 1 \right]^2,
\]

and the optimization problem considered is to find

\[
(\hat{\alpha}_{LS}, \hat{\beta}_{LS}) = \arg \min_{(\alpha, \beta) \in \mathbb{R}_+ \times \mathbb{R}_+} S_{LS}^2(\alpha, \beta).
\]

For the PTRP(\(\alpha, \beta\)) considered, the equality \(\sum_{i=1}^{N(\tau)} (t_i^\beta - t_{i-1}^\beta) = t_N^{\beta}\) holds, and consequently

\[
S_{LS}^2(\alpha, \beta) = \alpha^2 \sum_{i=1}^{N(\tau)} (t_i^\beta - t_{i-1}^\beta)^2 - 2\alpha t_N^{\beta} + N(\tau).
\] (5.14)

Substituting the value

\[
\alpha = \alpha_{LS}(\beta) = \frac{t_N^{\beta}}{\sum_{i=1}^{N(\tau)} (t_i^\beta - t_{i-1}^\beta)^2},
\] (5.15)

which minimizes the trinomial \(S_{LS}^2(\alpha, \beta)\), into formula (5.14) we have

\[
S_{LS}^2(\alpha_{LS}(\beta), \beta) = N(\tau) - \frac{t_N^{2\beta}}{\sum_{i=1}^{N(\tau)} (t_i^\beta - t_{i-1}^\beta)^2},
\]

and the optimization problem reduces to the problem of finding

\[
\hat{\beta}_{LS} = \arg \min_{\beta \in \mathbb{R}_+} \tilde{S}_{LS}^2(\beta),
\] (5.16)

where

\[
\tilde{S}_{LS}^2(\beta) = -\frac{t_N^{2\beta}}{\sum_{i=1}^{N(\tau)} (t_i^\beta - t_{i-1}^\beta)^2}.
\]
For numerical reasons (to avoid \(\ln 0\) in evaluating the estimator \(\hat{\beta}_{LS}\)), formula (5.14) is expressed in the form

\[
S_{LS}^2(\alpha, \beta) = \alpha^2 t_1^{2\beta} + \alpha^2 \sum_{i=2}^{N(\tau)} (t_i^{\beta} - t_{i-1}^{\beta})^2 - 2\alpha t_N^{\beta} + N(\tau).
\]

The condition \(\partial S_{LS}^2(\alpha, \beta)/\partial \beta = 0\) leads to the equation

\[
2\alpha \left[ \alpha t_1^{2\beta} \ln t_1 - t_N^{\beta} \ln t_N + \alpha \sum_{i=2}^{N(\tau)} \left( t_i^{\beta} - t_{i-1}^{\beta} \right) \left( t_i^{\beta} \ln t_i - t_{i-1}^{\beta} \ln t_{i-1} \right) \right] = 0.
\]

Taking into account formula (5.15) gives

\[
t_1^{2\beta} \ln t_1 - \ln t_N \sum_{i=1}^{N(\tau)} \left( t_i^{\beta} - t_{i-1}^{\beta} \right)^2 + \sum_{i=2}^{N(\tau)} \left( t_i^{\beta} - t_{i-1}^{\beta} \right) \left( t_i^{\beta} \ln t_i - t_{i-1}^{\beta} \ln t_{i-1} \right) = 0,
\]

which can be rewritten in the form

\[
t_1^{2\beta} \ln \frac{t_1}{t_N} + \sum_{i=2}^{N(\tau)} \left( t_i^{\beta} - t_{i-1}^{\beta} \right) \left( t_i^{\beta} \ln \frac{t_i}{t_N} - t_{i-1}^{\beta} \ln \frac{t_{i-1}}{t_N} \right) = 0. \tag{5.17}
\]

Consequently, we have

**Proposition 5.5.1** The **LS estimators** \(\hat{\alpha}_{LS}\) and \(\hat{\beta}_{LS}\) of \(\alpha\) and \(\beta\) are determined by

\[
\hat{\alpha}_{LS} = \frac{t_{N(\tau)}^{\beta_{LS}}}{\sum_{i=1}^{N(\tau)} \left( t_i^{\beta_{LS}} - t_{i-1}^{\beta_{LS}} \right)^2} \tag{5.18}
\]

and the \(\hat{\beta}_{LS}\) which is the solution to equation (5.17). \(\square\)

### 5.5.2 The CLS method

Using the CLS method we denote

\[
C(\tau) = \left\{ (\alpha, \beta) : \Lambda(t_N; \alpha, \beta) = N(\tau) \right\}, \tag{5.19}
\]

and the optimization problem considered is to find

\[
(\hat{\alpha}_{CLS}, \hat{\beta}_{CLS}) = \arg \min_{(\alpha, \beta) \in C(\tau)} S_{LS}^2(\alpha, \beta).
\]
For the PTRP($\alpha, \beta$) considered the restriction set defined by (5.19) takes the form

$$C(\tau) = \{ (\alpha, \beta) : \alpha t_\beta N(\tau) = N(\tau) \}.$$ 

Denote

$$\alpha_{CLS} = \alpha_{CLS}(\beta) = \frac{N(\tau)}{t_\beta N(\tau)}$$

and

$$S_{CLS}^2(\beta) = S_{LS}^2(\alpha_{CLS}(\beta), \beta).$$

Thus, under the CLS criterion the optimization problem reduces to the problem of finding

$$\hat{\beta}_{CLS} = \arg \min_{\beta \in \mathbb{R}^+} S_{CLS}^2(\beta),$$

where

$$S_{CLS}^2(\beta) = \frac{N^2(\tau)}{t^2_\beta N(\tau)} \sum_{i=1}^{N(\tau)} (t_\beta^i - t_\beta^{i-1})^2 - 2 \frac{N(\tau)}{t_\beta N(\tau)}(t_\beta^\tau N(\tau) + N(\tau))$$

$$= N(\tau) \left( \frac{N(\tau)}{t^2_\beta N(\tau)} \sum_{i=1}^{N(\tau)} (t_\beta^i - t_\beta^{i-1})^2 - 1 \right).$$

Hence, the problem of finding the estimator $\hat{\beta}_{CLS}$ is equivalent to the problem of finding

$$\hat{\beta}_{CLS} = \arg \min_{\beta \in \mathbb{R}^+} \tilde{S}_{CLS}^2(\beta),$$

where

$$\tilde{S}_{CLS}^2(\beta) = \frac{1}{t^2_\beta N(\tau)} \sum_{i=1}^{N(\tau)} (t_\beta^i - t_\beta^{i-1})^2.$$

Observe that

$$\tilde{S}_{CLS}^2(\beta) = - \left[ \frac{S_{LS}^2(\beta)}{S_{LS}^2(\beta)} \right]^{-1}$$

and the extrema appear at the same points as in the LS method, so $\hat{\beta}_{CLS} = \hat{\beta}_{LS}$. 

The condition $\partial S_{CLS}^2(\beta)/\partial \beta = 0$ leads to the equation
\[
t_i^{2\beta} \ln \frac{t_i}{t_{N(\tau)}} + \sum_{i=2}^{N(\tau)} \left( t_i^{\beta} - t_{i-1}^{\beta} \right) \left( t_i^{\beta} \ln \frac{t_i}{t_{N(\tau)}} - t_{i-1}^{\beta} \ln \frac{t_{i-1}}{t_{N(\tau)}} \right) = 0, \tag{5.21}
\]
which has the same form as that one defined by (5.17) for deriving $\hat{\beta}_{LS}$ in the LS method.

**Proposition 5.5.2** The CLS estimators $\hat{\alpha}_{CLS}$ and $\hat{\beta}_{CLS}$ of $\alpha$ and $\beta$ are determined by
\[
\hat{\alpha}_{CLS} = \frac{N(\tau)}{t_{N(\tau)}^{\beta_{CLS}}},
\]
and the $\hat{\beta}_{CLS}$ which is the solution to equation (5.21).

### 5.5.3 The M method

For the PTRP$(\alpha, \beta)$ considered, the system of equations of (5.13) takes the form
\[
\begin{cases}
\alpha t_{N(\tau)}^\beta = N(\tau), \\
\alpha^2 \sum_{i=1}^{N(\tau)} (t_i^\beta - t_{i-1}^\beta)^2 = (s + 1)N(\tau) - s.
\end{cases}
\]
Thus we have the following

**Proposition 5.5.3** The M estimators $\hat{\alpha}_M$ and $\hat{\beta}_M$ of $\alpha$ and $\beta$ are determined by
\[
\hat{\alpha}_M = \frac{N(\tau)}{t_{N(\tau)}^{\beta_M}},
\]
and the $\hat{\beta}_M$ which is the solution to the equation
\[
N^2(\tau) \left( \sum_{i=1}^{N(\tau)} \frac{t_i^{\beta} - t_{i-1}^{\beta}}{t_{N(\tau)}^{\beta}} \right)^2 = (s + 1)N(\tau) + s = 0. \tag{5.24}
\]

For numerical computation reasons the following equivalent form of equation (5.24)
\[
N^2(\tau) \left\{ \left( \frac{t_1}{t_{N(\tau)}} \right)^{2\beta} + \sum_{i=2}^{N(\tau)} \left[ \left( \frac{t_i}{t_{N(\tau)}} \right)^{\beta} - \left( \frac{t_{i-1}}{t_{N(\tau)}} \right)^{\beta} \right]^2 \right\} -(s + 1)N(\tau) + s = 0 \tag{5.25}
\]
Recall here that for the WPLP($\alpha, \beta, \gamma$) the variance $s$ of the renewal distribution defined by $F$ is given by formula (3.10). In particular, $s = 1$ for the PLP($\alpha, \beta$).

5.6 Numerical results

In this section some numerical results are presented to illustrate the accuracy of the LS, CLS and M estimators proposed in the PTRP($\alpha, \beta$) model (with $F$ unspecified) and in the WPLP($\alpha, \beta, \gamma$). The samples of the PLP($\alpha, \beta$) and the WPLP($\alpha, \beta, \gamma$) were generated up to a fixed number $n$ of jumps is reached and for $k = 500$ samples for each chosen combination of the parameters $\alpha, \beta$ and $\gamma$. The estimates of the unknown parameters $\alpha, \beta$ and $\gamma$ are evaluated as the means of the estimates derived on the basis of individual realizations of the process considered. The variability of an estimator $\hat{\eta}$ of an unknown parameter $\eta$ was measured by the root mean squared error (RMSE) which is expressed by

$$\text{RMSE}(\hat{\eta}) = \sqrt{\text{sd}(\hat{\eta})^2 + (\text{mean}(\hat{\eta}) - \eta)^2},$$

where $\text{sd}$ stands for the standard deviation. In the tables the abbreviation $\text{se}(\hat{\eta})$ is used for this error.

In constructing the executable computer programs, procedures of the package Mathematica 8.0 were used.

5.6.1 The estimates in a PLP

The values of the estimators of $\alpha$ and $\beta$ were evaluated numerically using two numerical methods: constrained local optimization through solving equations (CLOSE method) and constrained global optimization (CGO method).

The CLOSE method in obtaining ML estimators relies on using the explicit formulae for $\hat{\alpha}_{ML}$ and $\hat{\beta}_{ML}$ given by (4.4) and (4.5), respectively, in Fact 4.2.1.

The CLOSE method in evaluating the LS estimators relies on Proposition 5.5.1, i.e. on solving numerically equation (5.17) with respect to $\beta > 0$ and then substituting the solution for the estimator $\hat{\beta}_{LS}$ into formula (5.18) for the estimator $\hat{\alpha}_{LS}$.

The CLOSE method in evaluating the CLS estimators relies on Proposition 5.5.2, i.e. on solving numerically equation (5.21) with respect to $\beta > 0$ and then substituting the solution for the estimator $\hat{\beta}_{CLS}$ into formula (5.22) for the estimator $\hat{\alpha}_{CLS}$.

The M estimators were obtained by Proposition 5.5.3, i.e. by solving numerically equation (5.25) (for $s = 1$) with respect to $\beta > 0$ and then substituting the solution for the estimator $\hat{\beta}_{M}$ into formula (5.23) for the estimator $\hat{\alpha}_{M}$.
To investigate the numerical results for those processes for which the optimization problems cannot be even partially solved explicitly (in contrast to the PLP(α, β)), an analogous numerical investigation is conducted by using CGO method. The CGO method in evaluating ML estimators relies on solving the problem \((\hat{\alpha}_{ML}, \hat{\beta}_{ML}) = \arg \max_{(\alpha, \beta) \in \mathbb{R}_+ \times \mathbb{R}_+} L(\tau; \alpha, \beta)\) or equivalently \((\hat{\alpha}_{ML}, \hat{\beta}_{ML}) = \arg \max_{(\alpha, \beta) \in \mathbb{R}_+ \times \mathbb{R}_+} \ell(\tau; \alpha, \beta)\) by using a constrained global optimization procedure with respect to both variables \(\alpha\) and \(\beta\).

The CGO method in evaluating LS and CLS estimators relies on solving the problems defined by (5.16) and (5.20), respectively, by using constrained global optimization procedures with respect to the variable \(\beta\), and then substituting the solutions into formulas (5.18) and (5.22), respectively. The results carried out by the CGO numerical method have had the same accuracy as those carried out by the CLOSE numerical method, and the latter are not presented in the paper.

The estimates \(\hat{\alpha}_{LS}, \hat{\alpha}_{CLS}, \hat{\beta}_{(C)LS}, \hat{\alpha}_{M} \) and \(\hat{\beta}_{M}\) proposed in the PTRP(α, β) are evaluated on the basis of the realizations (samples) of the generated PLP(α, β) and compared with the ML estimates \(\hat{\alpha}_{ML}\) and \(\hat{\beta}_{ML}\) for the latter model. The values of the estimators and their measures of variability are contained in Tables 5.1 – 5.4 for \(n = 50\), \(n = 100\) and for \(k = 500\) samples for each pair \((\alpha, \beta)\).

### 5.6.2 The estimates in the Weibull-power law TRP

The ML estimates \(\hat{\beta}_{ML}\) and \(\hat{\gamma}_{ML}\) of \(\beta\) and \(\gamma\) are found by maximizing the log-likelihood function in solving the optimization problem

\[
(\hat{\beta}_{ML}, \hat{\gamma}_{ML}) = \arg \max_{(\beta, \gamma)} \tilde{\ell}(n; (\varphi, \beta, \gamma)),
\]

by using a constrained global optimization (CGO) procedure, where \(\tilde{\ell}(n; (\varphi, \beta, \gamma))\) is given by (5.10) with \(\varphi = \tilde{\varphi}(\beta, \gamma)\) defined by (5.6). The ML estimate \(\hat{\alpha}_{ML}\) of \(\alpha\) is evaluated using formula (5.9) with \(\tilde{\varphi}\) defined by (5.7). In the optimization problem the procedure NMaximize of Mathematica package is used.

The tables provide the numerical results for the WPLP(α, β, γ) in comparison to a PTRP(α, β) (the TRP with unknown \(F\)). The CLS estimates \(\hat{\alpha}_{CLS}\) and \(\hat{\beta}_{CLS}\) of the parameters \(\alpha\) and \(\beta\) are evaluated on the basis of the realizations of the generated WPLP(α, β, γ) supposing that we do know nothing about the renewal distribution function \(F\), i.e., that we observe the PTRP(α, β). The estimates \(\hat{\alpha}_{CLS}\) and \(\hat{\beta}_{CLS}\) are evaluated using Proposition 5.5.2 and the CGO method. The estimates \(\hat{\alpha}_{M}\) and \(\hat{\beta}_{M}\) were obtained by Proposition 5.5.3 for \(s\) evaluated according to formula (3.10).
The values of the estimators and their measures of variability are contained in Tables 5.5 – 5.12. We assumed $n = 50$ and $n = 100$, and used $k = 500$ simulated realizations for every combination of the three parameters $\alpha$, $\beta$ and $\gamma$.

### 5.6.3 Some real data

Let us take into account some real data of failure times, namely the data set contained in the paper of Lindqvist et. al. (2003), given in Table 5.13. These data contain 41 failure times of a gas compressor with time censoring at time 7571 (days).

Supposing that the set of failure times of Table 5.13 forms a TRP belonging to the class of WPLP($\alpha, \beta, \gamma$), the ML estimates $\hat{\alpha}_{ML}, \hat{\beta}_{ML}$ and $\hat{\gamma}_{ML}$ of $\alpha, \beta$ and $\gamma$ have been evaluated and presented in Table 5.14. On the other hand, if no assumptions are made on the renewal distribution function $F$, the estimates $\hat{\alpha}_{CLS}$ and $\hat{\beta}_{CLS}$ of $\alpha$ and $\beta$ are given as the parameters of the PTRP($\alpha, \beta$).

As the results of Table 5.14 show, the real data of failure times considered can be recognized as the WPLP(0.048, 0.763, 0.842) or the PTRP(0.028, 0.823). In both cases, the estimates of $\beta$ are almost the same. In Table 5.14 the relative errors $re(\hat{\alpha}_{CLS}) = |\hat{\alpha}_{CLS} - \hat{\alpha}_{ML}|/\hat{\alpha}_{ML}$ and $re(\hat{\beta}_{CLS}) = |\hat{\beta}_{CLS} - \hat{\beta}_{ML}|/\hat{\beta}_{ML}$ are given too. For comparison, in Table 5.14 there are also given the sum of squares $SS_{CLS} := S^2_{LS}(\hat{\alpha}_{CLS}, \hat{\beta}_{CLS})$ and $SS_{ML} := S^2_{LS}(\hat{\alpha}_{ML}, \hat{\beta}_{ML})$, where $S^2_{LS}(\theta)$ is defined by (5.11). Note that the sum of squares $SS_{CLS}$ is somewhat smaller then $SS_{ML}$.

Let us denote by $ENF_{ML}(t) = \Lambda(t; \hat{\alpha}_{ML}, \hat{\beta}_{ML}) = \hat{\alpha}_{ML} t^{\hat{\beta}_{ML}}$ the estimated number of failures up to time $t$ evaluated on the basis of the ML estimators, and analogously by $ENF_{CLS}(t) = \Lambda(t; \hat{\alpha}_{CLS}, \hat{\beta}_{CLS}) = \hat{\alpha}_{CLS} t^{\hat{\beta}_{CLS}}$ the estimated number of failures up to time $t$ evaluated on the basis of the CLS estimators. In Table 5.15 we compare the estimated numbers of failures with the observed number of failures $ONF(t)$ for some chosen values of $t$. The CLS method provides satisfactory estimates of the number of failures.

### 5.7 Concluding remarks

A good performance of the estimators $\hat{\alpha}_{CLS}$ and $\hat{\beta}_{CLS}$ is observed, which are obtained by the CLS method. This method leads to satisfactory accuracy of these estimators in the TRP($F, \lambda(\cdot)$) model considered with unspecified $F$ in comparison to the ML estimators $\hat{\alpha}_{ML}$ and $\hat{\beta}_{ML}$ for this model with specified $F$.

The CLS method leads in average to more accurate estimators than the LS and M methods.
The LS method considerably underestimates the parameter $\alpha$. In most cases considered we have $\text{RMSE}(\hat{\alpha}_{CLS}) < \text{RMSE}(\hat{\alpha}_{LS})$, and in all cases, $\text{RMSE}(\hat{\alpha}_{CLS}) < \text{RMSE}(\hat{\alpha}_{M})$.

The RMSE($\hat{\alpha}_{M}$) is about two, or even more, times greater than the RMSE($\hat{\alpha}_{CLS}$). Similar remark concerns the RMSE($\hat{\beta}_{M}$) and RMSE($\hat{\beta}_{CLS}$).

In some cases the RMSE($\hat{\alpha}_{CLS}$) is even less than the RMSE($\hat{\alpha}_{ML}$), and the RMSE($\hat{\beta}_{CLS}$) is less than the RMSE($\hat{\beta}_{ML}$).

For a given number $n$ of failures, the RMSE’s of all the estimators in the WPLP($\alpha, \beta, \gamma$) become significantly smaller as the parameter $\gamma$ increases. Remark that, according to formula (3.10), the variance $s$ of the renewal distribution $F$ decreases evidently as $\gamma$ increases. For example, $s = 1$ for $\gamma = 1$, $s = 0.2732$ for $\gamma = 2$, $s = 0.0787$ for $\gamma = 4$. A smaller value of $\gamma$ (a larger value of the variance $s$) causes larger variability of the estimators (recall that the RMSE determines the mean squared deviation of the estimate from the true value of the parameter – the risk). In the WPLP($\alpha, \beta, 1$), i.e. in the PLP($\alpha, \beta$), the variance of $F$ is equal to 1 and constitutes a great value in reference to the same value of the expectation of the renewal distribution as well as in reference to the assumed value 1 of the sample mean of the transformed working times $W_i = \Lambda(T_i) - \Lambda(T_{i-1}), i = 1, \ldots, N(\tau)$.

A great value, such as 1, of the variance of the renewal distribution causes larger variability and instability of the RMSE’s of the LS, CLS and M estimators in the case of relatively small sample sizes $n$. It may then happen that in some cases for $\gamma = 1$ the RMSE($\hat{\alpha}_{LS}$), RMSE($\hat{\alpha}_{CLS}$) and/or RMSE($\hat{\alpha}_{M}$) increase as $n$ increases. Further simulation study for $\gamma = 1$ and much greater than $n = 100$ numbers of failures shows that these RMSE’s decrease as $n$ increases. They decrease much more slowly than the RMSE’s of the parameter $\beta$.

For $\gamma \geq 2$, the RMSE($\hat{\alpha}_{CLS}$) decreases as $n$ increases.

If the number of jumps $n$ increases then all the RMSE’s of the parameter $\beta$, i.e. the RMSE($\hat{\beta}_{ML}$), RMSE($\hat{\beta}_{CLS}$) and RMSE($\hat{\beta}_{M}$) decrease.

If the renewal distribution function is unknown, then using the CLS method is recommended to obtain the estimators of the unknown parameters of the trend function or the expected number of failures.

The CLS method can also be used to predict the next failure time. Examination of asymptotic properties of the CLS estimators would be desirable, among others, for constructing the confidence intervals for unknown parameters or for the expected number of failures.

Chapter 6

Parameter Estimation in Non-homogeneous Poisson Process Models for Software Reliability

6.1 The software reliability model

In this chapter a subclass of non-homogeneous Poisson processes is considered, which besides of its theoretically interesting structure it can be used to model software reliability. As alternative to the ML method, two other methods are proposed for estimating parameters in the process models. It is demonstrated that in certain cases the ML estimators do not exist despite the fact that we have sufficient information in the form of a large number of faults observed. The methods proposed yield satisfactory estimates of unknown parameters and can be also applied in some process models in which the ML estimators do not exist.

Let \( \{N(t), t \geq 0\} \) be a NHPP with intensity function \( \lambda(t) \) and the mean value function \( \Lambda(t) = \int_0^t \lambda(u)du \) (cumulative intensity) having the parametric form defined by (3.4). Since the model defined by (3.4) has bounded mean value function, this is the reason for which this model is more appropriate as a software reliability model than the NHPP’s with unbounded mean value function, because a software system contains only a finite number of faults.

As alternative to the ML method, for estimating parameters \( \alpha \) and \( \beta \) of the NHPP with the mean value function \( \Lambda(t; \alpha, \beta) \) one can use the LS method or the CLS method proposed in Section 5.4. The LS and/or the CLS method can be applied to the models for which the ML method fails. The LS and CLS methods
can also be used to predict the next failure time.

The methods proposed will be applied to the general NHPP software reliability model defined by (3.4) and, in particular, to the NHPP software reliability model defined by the following cumulative intensity

\[ \Lambda(t; \alpha, \beta) = \alpha \left[ 1 - \exp(-t/\beta) \sum_{j=0}^{k} \frac{(t/\beta)^j}{j!} \right], \quad \alpha, \beta > 0, \quad (6.1) \]

or equivalently, by

\[ \lambda(t; \alpha, \beta) = \alpha \frac{(t/\beta)^k}{\beta^k k!} \exp(-t/\beta). \quad (6.2) \]

The model defined by (6.1) is a special case of the model (3.4) and was first mentioned in the paper of Khoshgoftaar (1988). It is called the \textit{k-stage Erlangian NHPP software reliability model}.

In Section 6.6 some numerical results illustrating the accuracy of the proposed LS and CLS estimators with comparison to the ML estimators are presented for a special case of the Erlangian NHPP software reliability model.

### 6.2 ML method for the software reliability model

In particular, for the NHPP with the mean value function \( \Lambda(t; \vartheta) \), \( \vartheta = (\alpha, \beta) \), defined by (3.4), the \textbf{likelihood function} based on the observed arrival times \( t_1, t_2, \ldots, t_{N(T)} \) and \( N(T) \) takes the form

\[ L(\alpha, \beta) \propto \exp \left[ -\alpha F(T/\beta) \right] (\alpha/\beta)^{N(T)} \prod_{i=1}^{N(T)} f(t_i/\beta), \]

and the \textbf{log-likelihood function} is

\[ \log L(\alpha, \beta) \propto -\alpha F(T/\beta) + N(T) \log(\alpha/\beta) + \sum_{i=1}^{N(T)} \log f(t_i/\beta). \quad (6.3) \]

The value of \( \alpha \) maximizing the log likelihood function is

\[ \alpha = \frac{N(T)}{F(T/\beta)} =: \alpha_{ML}(\beta). \quad (6.4) \]

Substituting this value into formula (6.3) yields

\[ \log L(\alpha_{ML}(\beta), \beta) \propto -N(T) + N(T) \log \left[ \frac{N(T)}{\beta F(T/\beta)} \right] + \sum_{i=1}^{N(T)} \log f(t_i/\beta). \]
**Fact 6.2.1** The ML estimators $\hat{\alpha}_{ML}$ and $\hat{\beta}_{ML}$ of $\alpha$ and $\beta$ are determined by

$$\hat{\alpha}_{ML} = \frac{N(T)}{F(T/\hat{\beta}_{ML})}$$

(6.5)

and the $\hat{\beta}_{ML}$ which maximizes

$$\tilde{L}(\beta) := N(T) \log \left[ \frac{N(T)}{\beta F(T/\beta)} \right] + \sum_{i=1}^{N(T)} \log f(t_i)$$

(6.6)

with respect to $\beta$.

In particular, for the $k$-stage Erlangian NHPP software reliability model defined by (6.1), formulae (6.5) and (6.6) take the following form

$$\hat{\alpha}_{ML} = \frac{N(T)}{1 - \exp(-T/\hat{\beta}_{ML}) \sum_{j=0}^{k} \frac{(T/\hat{\beta}_{ML})^j}{j!}}$$

(6.7)

and

$$\tilde{L}(\beta) := N(T) \log \left[ \frac{N(T)}{\beta \left[ 1 - \exp(-T/\beta) \right] \sum_{j=0}^{k} \frac{(T/\beta)^j}{j!}} \right]$$

$$+ \sum_{i=1}^{N(T)} \log \left( \frac{t_i}{\beta} \right)^k - \frac{N(T)}{\beta} \sum_{i=1}^{N(T)} t_i$$

(6.8)

For the model with $k = 0$, formulae (6.7) and (6.8) have the following simple form

$$\hat{\alpha}_{ML} = \frac{N(T)}{1 - \exp(-T/\hat{\beta}_{ML})}$$

(6.9)

and

$$\tilde{L}(\beta) := N(T) \log \left[ \frac{N(T)}{\beta \left[ 1 - \exp(-T/\beta) \right]} \right] - \sum_{i=1}^{N(T)} \frac{t_i}{\beta}$$

(6.10)

### 6.3 The LS and CLS methods as alternatives to the ML method

The ML estimators of the parameters $\alpha$ and $\beta$ of the model (3.4) do not always exist. In particular, it follows from Theorem 2.1 of Zhao and Xie (1996) that for the model defined by (6.1) the ML estimators do not exist with the probability

$$P\left( \frac{1}{N(T)} \sum_{i=1}^{N(T)} t_i \geq \frac{k+1}{k+2} T \right),$$

where $N(T)$ is the number of arrivals up to time $T$ and $t_1, \ldots, t_{N(T)}$ are the arrival times observed.
6.3.1 The LS method for the software reliability model

For the NHPP with the cumulative intensity function defined by (3.4) the sum of squares of (5.11) takes the following form

\[ S_{LS}^2(\alpha, \beta) = \sum_{i=1}^{N(T)} \left[ \Lambda(t_i; \alpha, \beta) - \Lambda(t_{i-1}; \alpha, \beta) - 1 \right]^2 \]

\[ = \sum_{i=1}^{N(T)} [\alpha F(t_i/\beta) - \alpha F(t_{i-1}/\beta) - 1]^2 \]

\[ = \alpha^2 \sum_{i=1}^{N(T)} [F(t_i/\beta) - F(t_{i-1}/\beta)]^2 - 2\alpha F(t_{N(T)}/\beta) + N(T) \]  \hspace{1cm} (6.11)

Expression (6.11) regarded as a trinomial with respect to \( \alpha \) is minimized by

\[ \alpha = \alpha_{LS}(\beta) = \frac{F(t_{N(T)}/\beta)}{\sum_{i=1}^{N(T)} [F(t_i/\beta) - F(t_{i-1}/\beta)]^2} \]

Substituting this value into formula (6.11) yields

\[ S_{LS}^2(\alpha_{LS}(\beta), \beta) = N(T) - \frac{F^2(t_{N(T)}/\beta)}{\sum_{i=1}^{N(T)} [F(t_i/\beta) - F(t_{i-1}/\beta)]^2}. \]

Thus we have the following

**Proposition 6.3.1** The LS estimators \( \hat{\alpha}_{LS} \) and \( \hat{\beta}_{LS} \) of \( \alpha \) and \( \beta \) are determined by

\[ \hat{\alpha}_{LS} = \frac{F(t_{N(T)}/\hat{\beta}_{LS})}{\sum_{i=1}^{N(T)} [F(t_i/\hat{\beta}_{LS}) - F(t_{i-1}/\hat{\beta}_{LS})]} \]  \hspace{1cm} (6.12)

and the \( \hat{\beta}_{LS} \) which maximizes

\[ \tilde{S}_{LS}^2(\beta) = \frac{F^2(t_{N(T)}/\beta)}{\sum_{i=1}^{N(T)} [F(t_i/\beta) - F(t_{i-1}/\beta)]^2} \]  \hspace{1cm} (6.13)

with respect to \( \beta \).

The estimator \( \hat{\beta}_{LS} \) of the parameter \( \beta \) is a solution to the equation

\[ F(t_{N(T)}/\beta) \sum_{i=1}^{N(T)} [F(t_i/\beta) - F(t_{i-1}/\beta)][f(t_i/\beta)t_i - f(t_{i-1}/\beta)t_{i-1}] \]

\[ - f(t_{N(T)}/\beta)t_{N(T)} \sum_{i=1}^{N(T)} [F(t_i/\beta) - F(t_{i-1}/\beta)]^2 = 0. \]
6.3.2 The CLS method for the software reliability model

For the NHPP process considered the constraint given by (5.12) takes the form

\[
\frac{1}{N(T)} \sum_{i=1}^{N(T)} [\Lambda(t_i; \alpha, \beta) - \Lambda(t_{i-1}; \alpha, \beta)]
\]

\[
= \frac{\alpha}{N(T)} \sum_{i=1}^{N(T)} [F(t_i/\beta) - F(t_{i-1}/\beta)] = \frac{\alpha}{N(T)} F(t_{N(T)}/\beta) = 1.
\]

It then follows that

\[
\alpha = \frac{N(T)}{F(t_{N(T)}/\beta)} =: \alpha_{CLS}(\beta).
\]

Substituting this value into formula (6.11) we obtain

\[
S^2_{LS}(\alpha_{CLS}(\beta), \beta) = N(T) \left[ \frac{N(T) \sum_{i=1}^{N(T)} [F(t_i/\beta) - F(t_{i-1}/\beta)]^2}{F^2(t_{N(T)}/\beta)} - 1 \right].
\]

Thus we have the following

**Proposition 6.3.2** The CLS estimators \( \hat{\alpha}_{CLS} \) and \( \hat{\beta}_{CLS} \) of \( \alpha \) and \( \beta \) are determined by

\[
\hat{\alpha}_{CLS} = \frac{N(T)}{F(t_{N(T)}/\beta_{CLS})}
\]

and the \( \hat{\beta}_{CLS} \) which maximizes \( \tilde{S}^2_{LS}(\beta) \) given by (6.13).

Let us recall that the CLS estimate \( \hat{\beta}_{CLS} \) takes the same values as the estimate \( \hat{\beta}_{LS} \) in the LS method.

In general, the optimization problems consisting in finding the ML, LS and CLS estimators for a NHPP, with any mean value parametric function \( \Lambda(t; \alpha, \beta) \), can be defined by

\[
(\hat{\alpha}_{ML}, \hat{\beta}_{ML}) = \arg \max_{(\alpha, \beta) \in \mathbb{R}^+ \times \mathbb{R}^+} \log L(\alpha, \beta),
\]

\[
(\hat{\alpha}_{LS}, \hat{\beta}_{LS}) = \arg \min_{(\alpha, \beta) \in \mathbb{R}^+ \times \mathbb{R}^+} S^2_{LS}(\alpha, \beta),
\]

\[
(\hat{\alpha}_{CLS}, \hat{\beta}_{CLS}) = \arg \min_{(\alpha, \beta) \in C} S^2_{LS}(\alpha, \beta),
\]

(6.14)
respectively, where $L(\alpha, \beta)$ is the corresponding likelihood function, $S^2_{LS}(\alpha, \beta)$ is defined by (5.11) with $\vartheta = (\alpha, \beta)$, and the restriction set

$$C = \left\{ (\alpha, \beta) : \frac{1}{N(T)} \sum_{i=1}^{N(T)} [\Lambda(t_i; \alpha, \beta) - \Lambda(t_{i-1}; \alpha, \beta)] = 1 \right\}.$$

By Fact 6.2.1 and Propositions 6.3.1 and 6.3.2, for the NHPP defined by (3.4) we have the following

**Corollary 6.3.1** In the case of the NHPP defined by (3.4), the optimization problems (6.15), (6.16) and (6.17) reduce to the following ones

$$\hat{\beta}_{ML} = \arg\max_{\beta \in \mathbb{R}^+} \tilde{L}(\beta),$$

$$\hat{\beta}_{(C)LS} = \arg\max_{\beta \in \mathbb{R}^+} \tilde{S}^2_{LS}(\beta),$$

where $\tilde{L}(\beta)$ and $\tilde{S}^2_{LS}(\beta)$ are defined by (6.6) and (6.13), respectively. The ML, LS and CLS estimators $\hat{\alpha}_{ML}$, $\hat{\alpha}_{LS}$ and $\hat{\alpha}_{CLS}$ of the parameter $\alpha$ are determined by formulas (6.5), (6.12) and (6.14), respectively.

6.4 Remarks on consistency of the estimators

It follows from Zhao and Xie (1996) that the ML estimators of $\alpha$ and $\beta$ in the NHPP model defined by (3.5) are not consistent when the fixed total testing time $T$ tends to infinity.

Recently, Nayak, Bose and Kundu (2008) proved that for the NHPP models with the intensity function of the form $\lambda(t) = \mu f(\vartheta(t), 0 < \mu < \infty, \vartheta \in \Theta$, and satisfying the condition $\lim_{t \to \infty} \Lambda(t) < \infty$, there is no consistent estimator (not just the ML one) of a parametric function, say $\psi(\mu, \vartheta)$, if $\psi(\mu, \vartheta)$ is not a constant function of $\mu$. It then follows that there is no consistent estimator of $\alpha$ in the NHPP model considered.

6.5 Some special models

6.5.1 The $k$-stage Erlangian NHPP software reliability model

Let us consider the special case of the model defined by (3.4), where

$$F(t/\beta) = 1 - \exp(-t/\beta) \sum_{j=0}^{k} \frac{(t/\beta)^j}{j!},$$

(6.20)
Software reliability models

and

\[ f(t/\beta) = \frac{(t/\beta)^k}{k!} \exp(-t/\beta). \]

Thus this is the \( k \)-stage Erlangian NHPP software reliability model with the cumulated intensity function \( \Lambda(t; \alpha, \beta) \) and intensity function \( \lambda(t; \alpha, \beta) \) defined by (6.1) and (6.2), respectively. The parameter \( k \) is usually a small integer and it is assumed to be known.

The \( k \)-stage Erlangian software reliability model contains the exponential model proposed by Goel and Okumoto (1979) and the delayed \( s \)-shaped model studied by Yamada, Ohba and Osaki (1984) as special cases (with \( k = 0 \) and \( k = 1 \)). These two models are the most widely used NHPP software reliability models in practice.

Applying Propositions 6.3.1 and 6.3.2 to the \( k \)-stage Erlangian NHPP we obtain the following result.

**Proposition 6.5.3** For the \( k \)-stage Erlangian NHPP defined by (6.1) the LS and CLS estimators of \( \alpha \) and \( \beta \) are determined by

\[
\hat{\alpha}_{LS} = \frac{1 - \exp(-t_{N(T)}/\hat{\beta}) \sum_{j=0}^{k} \frac{(t_{N(T)}/\hat{\beta})^j}{j!}}{\sum_{i=1}^{N(T)} \left[ \exp(-t_{i-1}/\hat{\beta}) \sum_{j=0}^{k} \frac{(t_{i-1}/\hat{\beta})^j}{j!} - \exp(-t_i/\hat{\beta}) \sum_{j=0}^{k} \frac{(t_i/\hat{\beta})^j}{j!} \right]^2},
\]

\[
\hat{\alpha}_{CLS} = \frac{N(T)}{1 - \exp(-t_{N(T)}/\hat{\beta}) \sum_{j=0}^{k} \frac{(t_{N(T)}/\hat{\beta})^j}{j!}},
\]

and the \( \hat{\beta} \) which maximizes the function

\[
\bar{S}^2_{LS}(\beta) = \frac{1 - \exp(-t_{N(T)}/\hat{\beta}) \sum_{j=0}^{k} \frac{(t_{N(T)}/\hat{\beta})^j}{j!} \sum_{i=1}^{N(T)} \left[ \exp(-t_{i-1}/\hat{\beta}) \sum_{j=0}^{k} \frac{(t_{i-1}/\hat{\beta})^j}{j!} - \exp(-t_i/\hat{\beta}) \sum_{j=0}^{k} \frac{(t_i/\hat{\beta})^j}{j!} \right]^2}{\sum_{i=1}^{N(T)} \left[ \exp(-t_{i-1}/\hat{\beta}) \sum_{j=0}^{k} \frac{(t_{i-1}/\hat{\beta})^j}{j!} - \exp(-t_i/\hat{\beta}) \sum_{j=0}^{k} \frac{(t_i/\hat{\beta})^j}{j!} \right]^2}
\]

with respect to \( \beta \).

**6.5.2 The Goel and Okumoto model**

For \( k = 0 \) we have from Proposition 6.5.3 the following

**Corollary 6.5.2** For the Goel and Okumoto model the LS and CLS estimators of \( \alpha \) and \( \beta \) are determined by

\[
\hat{\alpha}_{LS} = \frac{1 - \exp(-t_{N(T)}/\hat{\beta})}{\sum_{i=1}^{N(T)} \left[ \exp(-t_{i-1}/\hat{\beta}) - \exp(-t_i/\hat{\beta}) \right]^2},
\]

(6.21)
\[ \hat{\alpha}_{\text{CLS}} = \frac{N(T)}{1 - \exp(-t_{N(T)}/\hat{\beta})}, \]  
(6.22)

and the \( \hat{\beta} \) which maximizes the function

\[ \tilde{S}_{LS}^2(\beta) = \frac{[1 - \exp(-t_{N(T)}/\beta)]^2}{\sum_{i=1}^{N(T)}[\exp(-t_{i-1}/\beta) - \exp(-t_{i}/\beta)]^2} \]  
(6.23)

with respect to \( \beta \).

\section*{6.6 Numerical results}

In this section, for a given values of pairs of the parameters \( \alpha \) and \( \beta \) in the Goel and Okumoto model we present some numerical results illustrating the accuracy of the proposed LS and CLS estimators of these parameters with comparison to the ML estimators. The numerical results are contained in Tables 6.1 – 6.16 for five observation times \( T = 0.5, 1, 2, 5, 10 \). The variability of an estimator \( \hat{\eta} \) of an unknown parameter \( \eta \) was measured by the root mean squared error which is defined by

\[ se(\hat{\eta}) = \sqrt{(sd(\hat{\eta}))^2 + (mean(\hat{\eta}) - \eta)^2}. \]

The tables contain the numerical results obtained on the basis of 2000 generated random samples (trajectories of the NHPP) for each pair \((\alpha, \beta)\).

The values of estimators of \( \alpha \) and \( \beta \) are evaluated using numerical constrained global optimization procedures to solve the problems (6.18) and (6.19) for the Goel and Okumoto model, i.e. for the functions \( \tilde{L}(\beta) \) and \( \tilde{S}_{LS}^2(\beta) \) defined by (6.10) and (6.23), respectively. The resulting estimates of \( \beta \) have been substituted into formulae (6.9), (6.21) and (6.22) to get estimates of \( \alpha \): \( \hat{\alpha}_{\text{ML}}, \hat{\alpha}_{\text{LS}} \) and \( \hat{\alpha}_{\text{CLS}} \), respectively. In constructing the executable computer program, procedures of the package Mathematica 8.0 were used.

The results given in Tables 6.1, 6.4 and 6.7 demonstrate that for short observation times \( T \) the ML estimators as well as the (C)LS estimators do not always exist. For example, for \( T = 0.5 \) and the pairs of the parameters \( \alpha \) and \( \beta \) numbered by No. 8 – 10 there is about 40 percentage of no-existence of the ML estimators as well as about 40 percentage of no-existence of the (C)LS estimators. However, there is about 10 percentage that the ML estimator does not exist, whereas the (C)LS estimator does exist. Note that in this case the ML estimator does not exist despite the fact that we have sufficient information in the form of a large number of faults observed in relatively short observation time. Table 6.16 gives the LS and CLS estimates of \( \alpha \) and \( \beta \) for some distinct cases in which the ML estimator does not exist, whereas the (C)LS estimator does exist. The table shows that in
some cases when the ML method fails one could apply the CLS method yielding satisfactory estimates.

In general, one observes a good performance of the CLS method. The numerical results show that the CLS method yields the estimates of $\alpha$ and $\beta$ which are practically so accurate as the ML estimates. The LS method considerably underestimates the parameter $\alpha$.

Tables 6.1, 6.4, 6.7, 6.10 and 6.13 demonstrate that the percentage of non-existence of the ML as well as the (C)LS estimators of $\alpha$ and $\beta$ tends to zero as $T$ grows. The likelihood function for this process is analytically tractable and it follows from the results of Zhao and Xie (1996) that the ML estimators exist with probability 1 as $T \to \infty$.

Legend:
MJN – the mean jump (fault) number (the estimate of the mean value of the process at time $T$),
MLJT – the mean last jump time,
DT – the difference time: $T - \text{MLJT}$,
RDT – the relative difference time: $(T - \text{MLJT})/\text{MLJT}$,
M’S– the percentage of non-existence of the ML estimator and existence of the (C)LS estimator,
MS’- the percentage of existence of the ML estimator and no-existence of the (C)LS estimator,
M’ - the percentage of no-existence of the ML estimator,
S’ - the percentage of no-existence of the (C)LS estimator.

renewal distribution function, 42
renewal process, 35
repairable system, 31
RP, 35

survival function, 1
survival time, 1

threshold-stability, 28
time truncation, 53
time-transformed exponential family, 29
trend function, 42
trend-renewal process, 42
TRP, 42
two-parameter exponential distribution, 14
waiting times, 31
wear-out failures, 7
Weibull distribution, 17
modified, 10
three parameter, 19
Weibull NHPP, 39
Weibull-Power Law TRP, 43
Weibull-power law TRP
simulation of, 48
working times, 31
WPLP, 43
simulation, 48

Weibull NHPP, 39
Weibull-Power Law TRP, 43
Weibull-power law TRP
simulation of, 48
working times, 31
WPLP, 43
simulation, 48
