Abstract

Approximately 90% of patients diagnosed with non-small cell lung cancer (NSCLC) die due to distant metastases. However, the complicated molecular and cellular mechanisms involved in lung cancer metastasis remain poorly understood. Copine III (CPNE3), a member of a Ca²⁺-dependent phospholipid-binding protein family, was identified as a novel metastasis-associated protein in NSCLC in our previous study, however, its function in metastasis remains unclear. Here, we found that CPNE3 was expressed at high levels in NSCLC tissues and advanced TNM stages and was significantly associated with poor prognosis. In addition, CPNE3 interacted with phosphorylated erb-b2 receptor tyrosine kinase 2 (pErbB2) and receptor of activated protein C kinase 1 (RACK1) and activated the focal adhesion (FA) signaling pathway in NSCLC cells. Moreover, knockdown of RACK1 inhibited cell motility in the CPNE3-overexpressed NSCLC cells. These findings offer mechanistic insights into the oncogenic roles of CPNE3 and the pivotal effects of CPNE3 as a biomarker and therapeutic target for NSCLC metastasis.

Key words: CPNE3, NSCLC, RACK1, FAK.

Introduction

Lung cancer remains the leading cause of cancer-related mortality worldwide for both men and women[1]. Non-small cell lung cancer (NSCLC) accounts for approximately 85–90% of lung cancer cases, and approximately 90% of NSCLC patients die due to distant metastases rather than the primary tumor[2]. Although NSCLC has been investigated in numerous molecular studies aimed at developing new treatment strategies, the 5-year overall survival rates remain at 4–17%, and 65% of NSCLC patients are classified at stages III and IV at diagnosis[3–5]. However, the exact underlying metastatic

mechanisms and development progress of NSCLC remain complex and poorly understood. The need to identify potential therapeutic targets to improve NSCLC treatment is urgent.

In our previous study, we found that CPNE3 was a novel oncogene in NSCLC, and it promoted NSCLC metastasis *in vitro* and *in vivo*[6]. CPNE3 possess two C2Ds (C2D-A and C2D-B) and an A domain; C2Ds are responsible for Ca²⁺-dependent membrane-binding properties and A domains bind proteins[7, 8], it may regulate molecular events at the interface of the cell membrane and cytoplasm. CPNE3

was identified as a ligand of ErbB2 and plays a more general role in carcinogenesis[9]. In prostate cancer, CPNE3 was reported to be a susceptibility gene[10], and miR-133b repressed CPNE3 expression[11]. Moreover, CPNE3 plays a pivotal role in other diseases. High expression of CPNE3 predicted an adverse prognosis in acute myeloid leukemia[12], and it was identified as a novel candidate gene for schizophrenia[13]. However, in NSCLC, the underlying mechanism of CPNE3 remains unknown.

In this study, we demonstrated that CPNE3 was highly expressed in NSCLC patients and was associated with poor outcomes. RNA-seq was performed, and it revealed that CPNE3 participates in the focal adhesion kinase (FAK) signaling pathway. To further investigate the underlying mechanism, we made use of co-immunoprecipitation and found that CPNE3 interacts with RACK1 and pErbB2, and the mobility potential in CPNE3 overexpression cells was reduced after knockdown of RACK1.

Materials and methods

Cell lines and cell culture

Two human NSCLC cell lines (SPC-A-1 and H1299) and human embryonic kidney 293T cells were used. SPC-A-1 cells were obtained from the Cellular Institute of Chinese Academy of Science (Shanghai, China) in 2007. H1299 and 293T cells were obtained from the American Type Culture Collection (ATCC). These cells were incubated at 37°C in a humidified air atmosphere containing 5% carbon dioxide in Dulbecco's modified Eagle's medium (DMEM) with 10% fetal bovine serum (FBS), 100 µ/ml penicillin (Sigma-Aldrich), and 100 µg/ml streptomycin (Sigma-Aldrich). These cell lines were mycoplasma-free and authenticated by quality examinations of morphology and growth profile.

Clinical NSCLC tissue samples

The 62 paired patient samples of primary NSCLC tissues and matched adjacent non-cancerous tissues were obtained from the Department of Cancer, Huashan Hospital affiliated with Shanghai Fudan University from 2014 to 2017. Tissue samples were acquired from the routine therapeutic surgery of patients who did not receive anti-tumor treatment. Upon resection, human surgical specimens were immediately frozen in liquid nitrogen and stored at -80°C. Informed consent was obtained from all patients, and the research was approved by the Ethics Committee of Shanghai Fudan University. We performed global mRNAs profiling with microarray analysis to screen metastasis-associated genes. Data are available via Gene Expression Omnibus (GEO). Online-available data sets were downloaded from

NCBI. 117 lung adenocarcinoma patients were involved in the Tomida' Cohort (<https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE13213>).

RNA isolation and quantitative real-time PCR assays

Total RNA samples from the cell lines and tissue samples used in this study were extracted with TRIzol reagent (Invitrogen, CA) according to the manufacturer's protocol and were quantified with Nanodrop 2000 (Thermo, Japan). A PrimeScript RT Reagent Kit (TaKaRa, China) was used to synthesize first-strand cDNA, which was used as the template for real-time polymerase chain reaction (qPCR). qPCR was performed three times with SYBR Green Premix Ex Taq (TaKaRa, China). The specific primers for the target genes are listed in Supplementary Table S1. Relative gene expression was analyzed in accordance with 7500 Software version 2.0.6 of Applied Biosystems. Gene expression levels were quantified according to the comparative $\Delta\Delta C_t$ method, and β -actin was used as the internal control.

Plasmid construction and transfection

For CPNE3 overexpression, full-length CPNE3 cDNA was obtained from Han's Lab (Xiamen, China) and was then cloned and inserted into the lentiviral expression vector pWPXL (Addgene). For CPNE3 knockdown, CPNE3-shRNA was obtained from Open Biosystems (Thermo, Japan). To produce the intended lentivirus, the constructed plasmids and lentiviral vector packaging system were transfected into HEK-293T cells using Lipofectamine 2000 Reagent (Invitrogen). After 48 hours, the supernatants from the HEK-293T cultures were collected to infect SPC-A-1/H1299 cells.

For RACK1 knockdown, RACK1-siRNAs were obtained from RiboBio (shanghai, China). Cells were transfected with the indicated siRNAs using Lipofectamine 2000 Reagent (Invitrogen). After transfection for 48 hours, the cells were used for migration, invasion, RNA extraction, and immunoblotting assays.

Cell migration and invasion assays

Cell migration and invasion assays were performed in a 24-well plate with 8 µm pore size chamber inserts (Corning). Per well, 5×10^4 cells (migration assays) and 1×10^5 cells (invasion assays) were inoculated into the upper chamber. For the invasion assays, the wells contained Matrigel-coated membrane, which was diluted with serum-free culture medium. In both assays, cells were suspended in 200 µl of DMEM without FBS. In the lower chamber, 800 µl of DMEM supplemented with 10% FBS was added. After the appropriate incubation

period, the cells that remained in the upper chamber were removed with a cotton swab, and the cells that moved to the bottom surface of the membrane were fixed with 100% methanol and stained with 0.1% crystal violet for 20 min. Then, the cells were imaged and counted under a CKX41 inverted microscope (Olympus, Japan). Assays were conducted independently three times.

Western blot analysis

The lysates were extracted from cultured cells and were then separated using 8% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE), followed by transferring onto nitrocellulose membranes (Millipore). Next, we blocked the membranes in 5% milk with phosphate-buffered saline. After one hour of blocking, the membranes were incubated with primary antibodies (Supplementary Table S2) at 4 °C overnight. The next day, the membranes were incubated with HRP-conjugated anti-mouse IgG (Sigma-Aldrich) or HRP-conjugated anti-rabbit IgG (Sigma-Aldrich) secondary antibodies (1:5000). Subsequently, visualization was performed with SuperSignal West Femto Maximum Sensitivity Substrate (Thermo, USA).

Co-immunoprecipitation

Co-immunoprecipitation was performed with SPC-A-1 pWPXL-CPNE3 cells. Equal amounts of protein (3000 µg) were preprocessed by protein A/G magnetic beads (Thermo Scientific). After two hours, the lysates were incubated with antibodies at 4 °C overnight, followed by an overnight incubation with beads. The next day, the beads were gently washed with phosphate-buffered saline (PBS) containing 1% Triton X-100 five times, and then the beads were loaded with 2× protein loading buffer at 100 °C for 10 min. IgG-bound, CPNE3-bound or RACK1-bound proteins were separated using SDS-PAGE and stained with a Coomassie brilliant blue R250 staining kit (Beyotime Biotechnology).

KEGG pathway analysis

To better interpret the RNA seq dataset generated, KEGG pathway annotations of the 849 significantly differentially expressed genes were analyzed using DAVID Bioinformatics Resources 6.8 (<https://david.ncifcrf.gov/>).

Statistical analysis

The quantitative variables are presented as the means and S.E.M unless otherwise noted and were analyzed by Student's t-test between the two groups (two-tailed; $p < 0.05$ was considered statistically significant). The overall survival time was defined as

the length of time between surgery and death. Figures were generated with GraphPad Prism 5 software. All analyses were performed with SPSS software (version 19.0, Armonk).

Results

CPNE3 is overexpressed and associated with poor outcomes in NSCLC patients

To assess the clinical significance of CPNE3, we analyzed CPNE3 RNA levels in 62 pairs of human NSCLC and their corresponding noncancerous lung tissues. Compared with corresponding nontumorous tissues, CPNE3 was significantly upregulated in NSCLC tissues (Fig. 1A). Moreover, the RNA expression levels of CPNE3 were upregulated in 69.4% (43/62) of NSCLC cases (Fig. 1B), and its expression was positively correlated with advanced TNM stages ($p = 0.024$) (Fig. 1C) and tumor sizes ($p = 0.048$), whereas CPNE3 levels were independent of age, gender, differentiation and metastasis (Supplementary Table S3). To better understand the impact of CPNE3 gene expression on the overall survival of lung cancer patients, we utilized NCBI Gene Expression Omnibus (GEO) datasets with accession number GSE13213 to assess the prognostic value of CPNE3. CPNE3 high/low mRNA expression was retrieved and identified according to the median value of gene expression. Importantly, high levels of CPNE3 RNA were remarkably associated with poor outcomes ($p < 0.001$) in the 117-GEO-patient cohort (Fig. 1D). The baseline data of the 117 lung cancer patients are reported in Supplementary Table S4. Taken together, our data show that CPNE3 is highly expressed in lung cancer and is related to clinical severity and prognosis.

CPNE3 regulates the FAK signaling pathway in NSCLC cell lines

To seek the potential mechanism and identify changes in gene expression of CPNE3 in NSCLC cells, RNA-seq was performed in H1299 sh-NC/sh-CPNE3 cells (Fig. 2A) and 849 genes were found to be altered after sh-CPNE3 transfection (Supplementary Table S5). KEGG pathway annotations of the genes were analyzed using DAVID Bioinformatics Resources 6.8, in which the top three pathways ($p < 0.05$) were Pathways in cancer, Neuroactive ligand-receptor interaction, and Focal adhesion (Figure 2B) (Supplementary Table S6). Then, 9 downregulated and 2 upregulated genes were selected for validation using qRT-PCR (Figure 2C), and we found that five genes, cartilage oligomeric matrix protein (COMP), integrin subunit alpha 11 (ITGA11), collagen type IV alpha 6 (COL4A6), Rac family small GTPase 2 (RAC2),

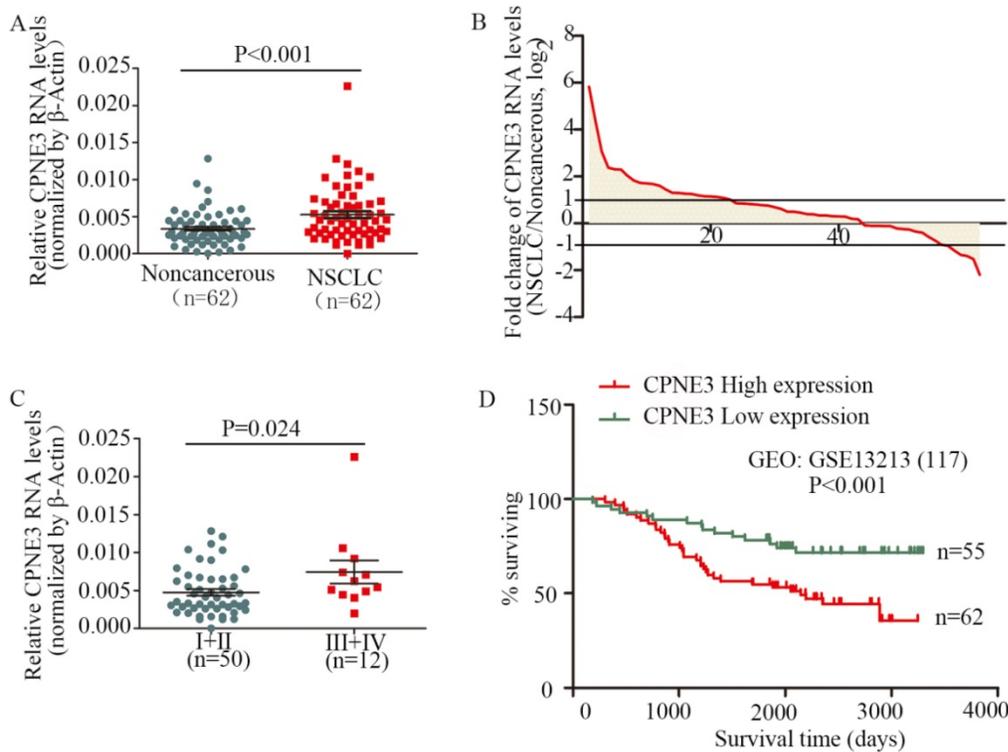

Figure 1. CPNE3 is overexpressed and associated with poor outcomes in NSCLC patients. (A) CPNE3 RNA levels were quantified in 62 pairs of NSCLC tissues and adjacent normal tissues using qPCR. (B) Fold changes in CPNE3 expression in 62 paired tissues (NSCLC/noncancerous; upexpression, >1; no change, -1~1; downexpression, <-1). (C) Clinical significance of CPNE3 in patients with NSCLC; high CPNE3 expression is positively correlated with TNM stage (III+IV). (D) Kaplan-Meier analyses of the correlation between CPNE3 RNA levels and overall survival in the 117-patient GEO cohort.

and cyclin D2 (CCND2) were associated with the FAK signaling pathway. Therefore, we detected five important well-known signaling molecules (FAK, phosphorylated FAK [pFAK], phosphatidylinositol-4-phosphate 3-kinase catalytic subunit type 2 alpha [PIK3C2A], ITGA11, and protein kinase C [PKC]) in this pathway, and the results showed that overexpression of CPNE3 significantly increased the signaling molecules in SPC-A-1 cells, but knockdown of CPNE3 led to a significant decrease in H1299 cells (Fig. 2D). Consequently, these results supported the idea that CPNE3 was a crucial gene in the FAK signaling pathway in NSCLC cell metastasis.

CPNE3 interacts with pErbB2 and RACK1 in NSCLC cells

To further determine the underlying mechanism of CPNE3 in NSCLC, we next identified the protein partners of CPNE3 in SPC-A-1 pWPXL-CPNE3 cells through co-immunoprecipitation assays. First, the SDS-PAGE gel was stained by Coomassie brilliant blue R250 after IgG or CPNE3 pull-down. It showed that there were some proteins precipitated by CPNE3 in the positions 25 KDa-35 KDa and 130 KDa-170 KDa (Fig. 3A). Because CPNE3 has been reported to be a ligand of ErbB2 and bound to RACK1 in breast cancer, and because of the gel stained indication, the

two proteins were selected for further investigation. We pulled down CPNE3 and probed for pErbB2 and RACK1, then found that CPNE3 specifically interacted with pErbB2 and RACK1, as shown in the immunoprecipitation assay (Fig. 3B). In addition, we pulled down RACK1 and probed for CPNE3 and pErbB2 and found that CPNE3 and pErbB2 were also precipitated by RACK1 in SPC-A-1 pWPXL-CPNE3 cells (Fig. 3C). Next, we examined whether the protein levels of RACK1 and pErbB2 were affected by CPNE3. This showed that overexpression of

CPNE3 in SPC-A-1 cells led to a significant increase in RACK1 and pErbB2 protein expression (Fig. 3D). Consequently, these results support the conclusion that CPNE3 interacts with RACK1 and pErbB2 and functions as a positive regulator of RACK1 and pErbB2 protein expression in NSCLC cells.

Knockdown of RACK1 inhibits NSCLC cell migration and invasion

Our findings demonstrated that CPNE3 interacted with RACK1 in NSCLC cells; however, whether CPNE3 functions through RACK1 is largely unknown. Since CPNE3 interacted with RACK1 and affected its protein expression, it is plausible that CPNE3 functions through RACK1 and RACK1 has an important role in NSCLC cell metastasis[14]. To test this hypothesis, we knocked down RACK1 in CPNE3-overexpressed SPC-A-1 cells. Western blotting and qRT-PCR confirmed that RACK1 protein and mRNA levels were rescued (Fig. 4A and B). As hypothesized, RACK1 knockdown significantly reduced the CPNE3 overexpression-induced cell migration and invasion (Fig. 4C). The results revealed that CPNE3 might promote NSCLC cell migration and invasion via RACK1.

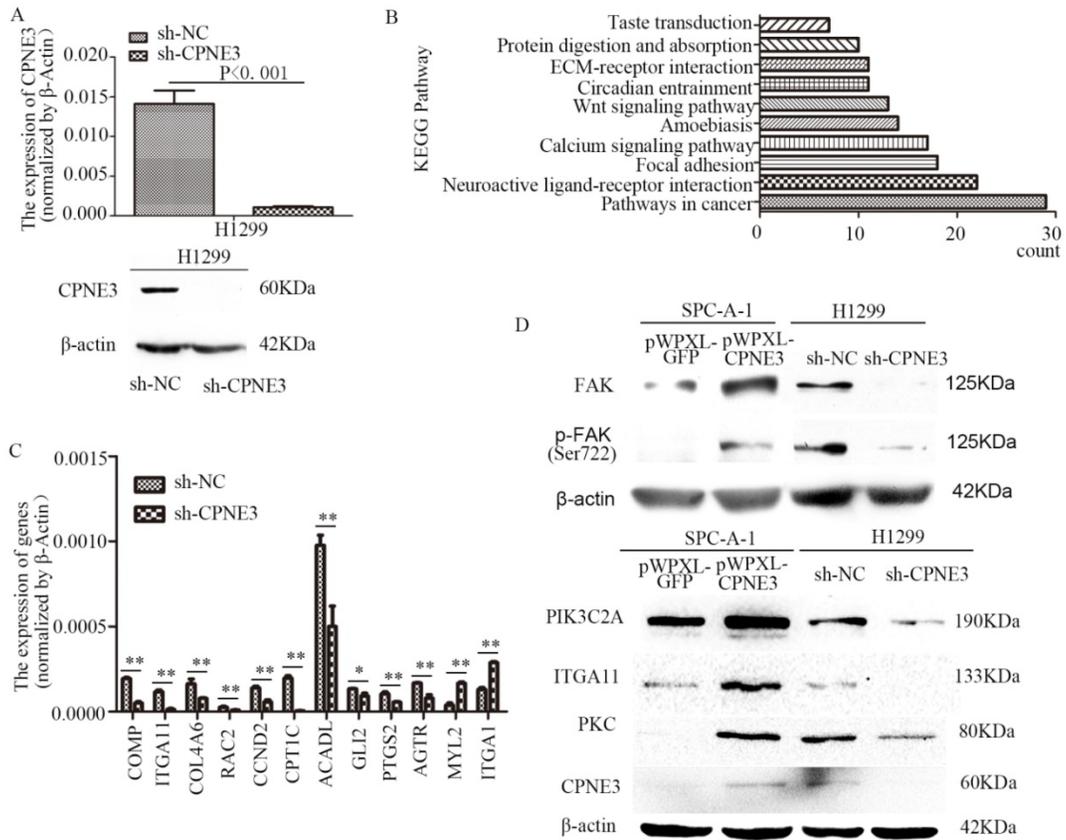

Figure 2. CPNE3 regulates the FAK signaling pathway in NSCLC cell lines. (A) Levels of mRNA and protein expression were validated after knockdown of CPNE3 in H1299 cells by qRT-PCR and western blotting. (B) The top ten KEGG pathways with p values <0.05. Data are representative of results from three independent experiments. * $p < 0.05$, ** $p < 0.01$ by Student's t-test.

Discussion

Currently, lung cancer has a 5-year survival rate that remains low, and metastatic spread is the leading cause of death of patients with NSCLC[3]. There is an urgent need for us to identify metastasis-related factors and to determine the underlying molecular mechanisms of NSCLC. In our previous study, we performed an iTRAQ proteomics approach on cell lines with different metastatic abilities and the same genomic background, which were derived from SPC-A-1 cells using a mouse-screening model[15], and CPNE3 was shown to be an oncogenic protein, promoting NSCLC metastasis *in vitro* and *vivo*[6]. It

was the first time that anyone had identified CPNE3 as a metastasis-associative protein in NSCLC, and our findings indicated that CPNE3 might play an important role in human carcinogenesis. Although several studies have investigated the role of CPNE3 in tumorigenesis, few researchers have elucidated the underlying mechanism in depth. There was only one report by C Heinrich, who suggested that CPNE3 interacts with ErbB2 and promotes tumor cell migration[9], but he did not investigate NSCLC. CPNE3 is a functional protein, and it is also involved in other diseases[16, 17]. However, the exact underlying metastatic mechanisms in NSCLC remain poorly understood.

In the present study, CPNE3 was significantly highly expressed in NSCLC tissues compared with matched noncancerous lung tissues. Moreover, the RNA expression of CPNE3 was upregulated in the majority of NSCLC cases (69.4%). Importantly, high levels of CPNE3 in lung cancer tissues are correlated with advanced tumor TNM stage and large tumor size. Although it was not found to be significant in metastasis, we discussed that this may be because of tumor heterogeneity and the low numbers of the NSCLC sample. Consistently, high levels of CPNE3 RNA were remarkably associated with poor outcomes. Our results also strongly suggested that CPNE3 was related to the clinical severity of NSCLC patients, and it could be considered to be a clinical biomarker of prognosis in NSCLC.

Next, RNA-seq was used to compare the changes in gene expression after stable knockdown of CPNE3 in H1299 cells, and 849 genes were found to be altered, among which 494 genes were upregulated and 355 genes were downregulated. KEGG pathway analysis was performed on the dysregulated genes, revealing that these genes were involved in pathways involved in cancer, neuroactive ligand-receptor interaction, and focal adhesion. These results provide valuable information for further study of the molecular mechanisms in NSCLC metastasis. Furthermore, 9 downregulated and 2 upregulated genes were selected for validation using qRT-PCR, and they were all consistent with the findings of RNA-seq. Interestingly, we found that COMP, ITGA11, COL4A6, RAC2, and CCND2 were associated with the FAK signaling pathway[18-20], which plays a fundamental role in cancer progression and metastasis[21, 22]. The focal adhesion proteins such as FAK, regulate cell spreading, adhesion, migration, proliferation and angiogenesis, and FAK expression correlates with tumor invasion, metastatic potential and poor disease outcome[23]. Consistently, our results suggested that overexpression of CPNE3 significantly increased the protein levels of FAK and pFAK and the key proteins (PIK3C2A, ITGA11, PKC) in the FAK signaling pathway. In contrast, knockdown of CPNE3 significantly reduced those proteins. The results indicated to us that CPNE3 might work as a pivotal protein in the FAK pathway in NSCLC metastasis, and further study is necessary to determine how CPNE3 affects the pathway.

In the present study, co-immunoprecipitation was performed to explore the protein partners of CPNE3 in NSCLC cells. According to the gel staining, ErbB2 and RACK1 were reported to interact with CPNE3 in breast cancer[9], and so they were selected for further investigation. Consistently, our present evidence supported that CPNE3 interacted with

pErbB2 and RACK1 in NSCLC cells. Furthermore, it was demonstrated that CPNE3 significantly increased pErbB2 and RACK1 protein levels. How does Copine-III interact with pErbB2 and RACK1? We had said that CPNE3 possessed two C2Ds, and C2Ds had been classified as Type I and Type II[24] and the Type II C2D of PKC has been shown to directly bind specific pTyr-containing peptides[25]. According to our results, we consider it likely that Copine-III directly binds pErbB2 (pTyr1248). However, the manner by which the three proteins interact with each other requires further study.

ErbB2 has been shown to have a pivotal role in various types of human cancer, and the metastatic mechanism of ErbB2 is well known in NSCLC[26, 27], so we focused our attention on RACK1. RACK1 is a member of the tryptophan-aspartate repeat (WD-repeat) family of proteins[28]. Many studies have reported on the role of RACK1 in tumorigenesis, and there are accumulating evidences now demonstrate multiple roles for RACK1 in regulating migration and invasion of tumour cells, including NSCLC [14]. A study in non-small cell lung cancer, found that RACK1 mediates the assembly of a RACK1-PP2A-Akt signalling complex in response to EphB3 activation which results in reduced Akt phosphorylation and inhibition of cell migration [29]. It suggests that RACK1 may act as a scaffolding protein, recruiting proteins to various transmembrane receptors and providing a platform for protein-protein interactions. RACK1 participates in numerous signaling events, and RACK1 was shown to associate with and be required for FAK activation [30, 31]. There are evidences that Copine-III binds RACK1 and colocalizes with pFAK in the migrating front of breast cancer cells [9]. Furthermore, Fei L et al. indicated that RACK1 promoted cellular proliferation by regulating G1/S progression in NSCLC cells[32]. Our previous findings demonstrated that overexpression of CPNE3 promoted NSCLC cell metastasis and proliferation. In the present study, we found that knockdown of RACK1 expression reduced cell migration and invasion ability in the CPNE3-overexpressed NSCLC cells, therefore demonstrating that CPNE3's effect on cell mobility and proliferation might largely dependent on RACK1, and then activate FAK pathway. Interestingly, C2 regulatory regions were found in a diverse range of proteins in addition to PKC and were the first protein domains identified capable of interacting with RACK1 [33], which are conserved in Copine-III C2D-B. Therefore, it might be possible that RACK1, which is thought to direct PKCs to specific membrane locations [34], might also direct interact with Copine-III, and might be affected its expression at the transcription level. Taken together,

we favor the hypothesis that CPNE3 promotes migration and invasion in non-small cell lung cancer by interacting with RACK1 via FAK signaling activation.

In summary, we identified a metastasis-related protein CPNE3 that is highly expressed in NSCLC tissues and is associated with poor patient survival. In addition, CPNE3 interacts with pErbB2 and RACK1 and activates the FAK signaling pathway in NSCLC cells. Moreover, knockdown of RACK1 inhibits cell migration and invasion ability in CPNE3-overexpressing NSCLC cells. Collectively, our study offers mechanistic insights into the oncogenic roles of CPNE3 and the pivotal effects of CPNE3 as a biomarker and therapeutic target for NSCLC metastasis.
