Abstract

A “string graph” is the intersection graph of a set of curves in the plane. It is known [9] that there are string graphs with clique number two and chromatic number arbitrarily large, and in this paper we study the induced subgraphs of such graphs.

Let us say a graph $H$ is “pervasive” (in some class of graphs) if for all $\ell \geq 1$, and in every graph in the class of bounded clique number and sufficiently large chromatic number, there is an induced subgraph which is a subdivision of $H$, where every edge of $H$ is replaced by a path of at least $\ell$ edges.

In an earlier paper [4] we showed that $K_3$ is pervasive (in the class of all graphs).

Which graphs are pervasive in the class of string graphs? It was proved in [3] that every such graph is a “forest of chandeliers”: roughly, every block is obtained from a tree by adding a vertex adjacent to its leaves, and there are rules about how the blocks fit together. In this paper we prove the converse, that every forest of chandeliers is pervasive in string graphs. Indeed, for many forests of chandeliers $H$, and many other graphs, every string graph with bounded clique number and sufficiently large chromatic number contains $H$ as an induced subgraph. (This in fact implies the previous statement.)

In every string graph of very large chromatic number, some vertex has second neighbours with (quite) large chromatic number. This turns out to be a key fact: we will show that every forest of chandeliers is pervasive in every class of graphs with this property. Indeed, all that is needed is that for some fixed $r$, in every induced subgraph of very large chromatic number, some vertex has $r$th neighbours with large chromatic number.

General graphs, with no such number $r$, are more difficult to handle: we suspect that every forest of chandeliers $H$ is pervasive in the class of all graphs, but so far we have only proved this for a few graphs $H$ such as the complete bipartite graph $K_{2,n}$. 
1 Introduction

All graphs in this paper are finite and simple, and if \(G\) is a graph, \(\chi(G)\) denotes its chromatic number, and \(\omega(G)\) denotes its clique number, that is, the cardinality of the largest clique of \(G\). This is the fifth in a series of papers on the induced subgraphs that must be present in graphs that have bounded clique number and (sufficiently) large chromatic number. The series was originally motivated by three conjectures of Gyárfás from 1985 [7] concerning the various lengths of induced cycles in such graphs, but we have already proved two of these, in [11] and [4] respectively:

1.1 For every integer \(k \geq 0\), every graph \(G\) with \(\omega(G) \leq k\) and \(\chi(G)\) sufficiently large contains an induced cycle of odd length at least 5.

1.2 For all integers \(k, \ell \geq 0\), every graph \(G\) with \(\omega(G) \leq k\) and \(\chi(G)\) sufficiently large contains an induced cycle of length at least \(\ell\).

We may ask, if \(G\) has bounded clique number and very large chromatic number, which graphs must be present in \(G\) as an induced subgraph? No graph has this property except for forests, because \(G\) can have arbitrarily large girth (and it is an open conjecture of Gyárfás [6] and Sumner [12] that forests do have this property). This is an interesting question but we have nothing to say about it here.

We may ask instead for the graphs \(H\) such that every graph \(G\) with bounded clique number and sufficiently large chromatic number must contain an induced subgraph which is a subdivision of \(H\). This certainly yields a larger class of graphs; for instance, every cycle has this property, in view of 1.2, and so does every forest, by a theorem of [10], and perhaps so do many more graphs. Solving it would considerably extend 1.2, but unfortunately this too still seems out of reach.

This paper is concerned with subdivisions of a graph, so let us clarify some definitions before we go on. Let \(H\) be a graph, and let \(H'\) be a graph obtained from \(H\) by replacing each edge \(uv\) by a path (of length at least one) joining \(u, v\), such that these paths are vertex-disjoint except for their ends. We say that \(H'\) is a subdivision of \(H\); and it is a proper subdivision of \(H\) if all the paths have length at least two. If each of the paths has exactly \(\ell + 1\) edges we call it an \(\ell\)-subdivision; if they each have at least \(\ell + 1\) edges it is a \((\geq \ell)\)-subdivision; and if they all have at most \(\ell + 1\) it is a \((\leq \ell)\)-subdivision.

If they all have length at least two and at most \(\ell + 1\) it is a proper \((\leq \ell)\)-subdivision.

Here is what seems to be a more tractable question of the same type, solving which would also extend 1.2. Let us say a graph \(H\) is pervasive in some class of graphs \(C\) if for all \(\nu, \ell \geq 0\) there exists \(c\) such that for every graph \(G \in C\) with \(\omega(G) \leq \nu\) and \(\chi(G) > c\), there is an induced subgraph of \(G\) isomorphic to a \((\geq \ell)\)-subdivision of \(H\). We say \(H\) is pervasive if it is pervasive in the class of all graphs. Which graphs are pervasive?

If \(H'\) is a subdivision of \(H\), then \(H'\) is pervasive if and only if \(H\) is pervasive; and 1.2 is equivalent to the statement that all cycles are pervasive (and also equivalent to the assertion that \(K_3\) is pervasive). By the theorem of [10], all forests are pervasive; but what else?

There is a beautiful example of Pawlik, Kozik, Krawczyk, Lasoń, Micek, Trotter and Walczak [9]; they found a sequence of graphs \(SP_k\) for \(k = 1, 2, \ldots\), each with clique number at most two and with chromatic number at least \(k\). (The same construction was found by Burling [2], but its significance was first pointed out in [9].) Furthermore, it is a string graph, the intersection graph of some set of curves in the plane; and consequently there are many graphs \(H\) such that no \((\geq 2)\)-subdivision of \(H\) appears in any \(SP_k\) as an induced subgraph. For every pervasive graph \(H\), some \((\geq 2)\)-subdivision

1
of $H$ must appear in some $SP_k$ as an induced subgraph, and this severely restricts the possibilities for which graphs might be pervasive. This was analyzed in a paper by Chalopin, Esperet, Li and Ossona de Mendez [3], which we explain next.

Let $T$ be a tree with $|V(T)| \geq 2$, and let $H$ be obtained from $T$ by adding a new vertex $v$ and making $v$ adjacent to every leaf of $T$ (and to no other vertex). Then $H$ is called a chandelier with pivot $v$. (We also count the one- and two-vertex complete graphs as chandeliers, when some vertex is chosen as pivot.) More generally, if we start with a chandelier, and repeatedly take a new chandelier, and identify its pivot with some vertex of what we have already built, what results is called a tree of chandeliers. If every component of $G$ is a tree of chandeliers, $G$ is called a forest of chandeliers. Chalopin, Esperet, Li and Ossona de Mendez [3] proved:

1.3 For every graph $H$, there is a ($\geq 2$)-subdivision of $H$ that appears as an induced subgraph in $SP_k$ for some $k$, if and only if $H$ is a forest of chandeliers.

It follows that every pervasive graph is a forest of chandeliers; and perhaps the converse is true, that every forest of chandeliers is pervasive. Whether that is true or not, the goal of this paper is to begin to determine which graphs are pervasive; and we achieve this goal for a class of graphs that includes the string graphs. We only have to consider forests of chandeliers, and they have the convenient property that every subdivision of a forest of chandeliers is another forest of chandeliers. Thus, if we could prove that for every forest of chandeliers $H$, every graph with bounded clique number and sufficiently large chromatic number contains a subdivision of $H$ as an induced subgraph, then it would follow that every forest of chandeliers is pervasive. We can therefore forget about looking for ($\geq \ell$)-subdivisions, and just look for subdivisions.

It is helpful to break this problem down into two steps, which we describe next. If $X \subseteq V(G)$, the subgraph of $G$ induced on $X$ is denoted by $G[X]$, and we often write $\chi(X)$ for $\chi(G[X])$. The distance between two vertices $u, v$ of $G$ is the length of a shortest path between $u, v$, or $\infty$ if there is no such path. If $v \in V(G)$ and $\rho \geq 0$ is an integer, $N^\rho_G(v)$ or $N^\rho(v)$ denotes the set of all vertices $u$ with distance exactly $\rho$ from $v$, and $N^\rho_G[v]$ or $N^\rho[v]$ denotes the set of all $v$ with distance at most $\rho$ from $v$. If $G$ is a nonnull graph and $\rho \geq 1$, we define $\chi^\rho(G)$ to be the maximum of $\chi(N^\rho[v])$ taken over all vertices $v$ of $G$. (For the null graph $G$ we define $\chi^\rho(G) = 0$.) Let $\mathbb{N}$ denote the set of nonnegative integers, and let $\phi : \mathbb{N} \to \mathbb{N}$ be a non-decreasing function. For $\rho \geq 1$, let us say a graph $G$ is $(\rho, \phi)$-controlled if $\chi(H) \leq \phi(\chi^\rho(H))$ for every induced subgraph $H$ of $G$. Roughly, this says that in every induced subgraph $H$ of $G$ with large chromatic number, there is a vertex $v$ such that $\chi(N^\rho_G[v])$ has large chromatic number. Let us say a class of graphs $\mathcal{C}$ is $\rho$-controlled if there is a non-decreasing function $\phi : \mathbb{N} \to \mathbb{N}$ such that every graph in the class is $(\rho, \phi)$-controlled.

Suppose that we are trying to prove that every graph with bounded clique number and sufficiently large chromatic number has some induced subgraph with property $X$, whatever that may be. In other words, we wish to show that for all $\nu \geq 0$ there exists $n$ such that for every graph $G$, if no induced subgraph has property $X$, and $\omega(G) \leq \nu$, then $\chi(G) \leq n$. We proceed by induction on $\nu$; so fix some $\nu$, such that the result holds for all smaller $\nu$. Let $\mathcal{C}$ be the class of all graphs $G$ with $\omega(G) \leq \nu$ such that no induced subgraph of $G$ has property $X$. We have to prove an upper bound on the chromatic number of the members of $\mathcal{C}$. One way to do so would be to complete two steps:

- prove that $\mathcal{C}$ is $\rho$-controlled for some $\rho \geq 1$; and
- use this fact to prove an upper bound on the chromatic number of the members of $\mathcal{C}$.
Let us see in more detail what is involved in these two steps.

• For the first step, we need to find $\rho$ such that for all integers $c \geq 0$, there exists $n_c$ such that $\chi(G) \leq n_c$ for all $G \in \mathcal{C}$ with $\chi^\rho(G) \leq c$. If we can do this, then for each $c \geq 0$ we set $\phi(c) = \max_{0 \leq c' \leq c} n_{c'}$ (or just arrange that the sequence $n_0, n_1, \ldots$ is nondecreasing, and set $\phi(c) = n_c$ for each $c$); then every $G \in \mathcal{C}$ is $(\rho, \phi)$-controlled, and so $\mathcal{C}$ is $\rho$-controlled.

• For the second step, we are given that $\mathcal{C}$ is $\rho$-controlled. We only need to prove an upper bound on $\chi(G)$ ($G \in \mathcal{C}$) for this given choice of $\rho$; but to do so we prove something more general. We prove that for all choices of $\rho$, and every $\rho$-controlled subclass $\mathcal{D} \subseteq \mathcal{C}$, there is an upper bound on the chromatic number of the members of $\mathcal{D}$. This approach has the advantage that we can use induction on $\rho$. The base case of this induction, when $\rho = 1$, is easy because of the induction on $\nu$. Consequently, we can assume that we are looking at a class $\mathcal{D}$ that is not $(\rho - 1)$-controlled; and that means that for some $c \geq 0$, there are induced subgraphs $H$ of members of $\mathcal{D}$, with $\chi^{\rho-1}(H) \leq c$ and with $\chi(H)$ arbitrarily large. (In our case, the arguments for $\rho = 2$ and for $\rho = 3$ are different from and more difficult than the argument for larger values of $\rho$.)

This is quite a powerful proof strategy, and we already use forms of it in several earlier papers; and we try to use it again, this time taking $X$ to be the property of being a subdivision of some fixed graph $H$.

In this paper we only carry out the step described in the second bullet above; the first bullet is giving us trouble, and so far we have managed it only for very simple-structured graphs $H$, such as the complete bipartite graph $K_{2,n}$. That being so, it seems that our success with the second bullet is wasted, unless we can complete the corresponding first bullet program. Fortunately not; for there are interesting graphs that automatically fall under the second bullet, and so our results will apply to them, whether we can complete the first bullet program or not. For instance, string graphs have this property; we will prove that the class of string graphs is 2-controlled.

For $m \geq 0$ and $r \geq 1$, we denote the $r$-subdivision of $K_{m,m}$ by $K_{m,m}^r$. A “lamp” (defined later) is a kind of graph more general than a chandelier, and we will define trees and forests of lamps; but some trees of chandeliers are not trees of lamps, because the composition rule is more restrictive. For every tree of chandeliers $H$ there is a tree of lamps $J$ such that some subdivision of $H$ is an induced subgraph of $J$, so the two classes are closely related.

Here are our results:

1.4 Let $\nu \geq 0$, let $H$ be a forest of lamps, and let $\mu \geq 0$. Let $\mathcal{C}$ be a 2-controlled class of graphs. Then there exists $c$ such that every graph $G$ in $\mathcal{C}$ with $\omega(G) \leq \nu$ and $\chi(G) > c$ contains one of $K_{\mu,\mu}^1$, $H$ as an induced subgraph.

Note the anomaly; for our purposes it would be enough to show that $G$ contains a subdivision of $H$ above, but in fact it will contain $H$ itself. Also, we remark that since $K_{\mu,\mu}^1$ (for $\mu$ sufficiently large) has an induced subgraph which is a 3-subdivision of $H$, for any graph $H$, it follows that under the same hypotheses, every graph $G$ in $\mathcal{C}$ with $\omega(G) \leq \nu$ and $\chi(G) > c$ contains one of $H, H^3$ as an induced subgraph.

1.5 For all $\rho \geq 2$, every forest of chandeliers is pervasive in every $\rho$-controlled class.
1.6 Let $\mu \geq 0$, and let $\rho \geq 2$. Let $C$ be a $\rho$-controlled class of graphs. The class of all graphs in $C$ that do not contain any of $K_{1,\mu}, \ldots, K_{\rho+2,\mu}$ as an induced subgraph is 2-controlled.

We will deduce that

1.7 The class of all string graphs is 2-controlled.

For string graphs, we have a strengthening of 1.5:

1.8 Let $\nu \geq 0$, and let $H$ be a forest of lamps. Then there exists $c$ such that every string graph with clique number at most $\nu$ and chromatic number greater than $c$ contains $H$ as an induced subgraph.

This implies:

1.9 A graph $H$ is pervasive for the class of string graphs if and only if $H$ is a forest of chandeliers.

Finally, we have a result about general graphs extending 1.2:

1.10 For all $n \geq 1$, the graph $K_{2,n}$ is pervasive.

2 Defining $SP_k$

Before we go on, let us digress to define $SP_k$. We will not need it in what follows, but there does not seem to be an explicit graph-theoretic description of it published, and our work was greatly influenced by the paper [3], which is based on this construction.

First, here is a composition operation. We start with a graph $A$, and a stable subset $S$ of $A$. Let $S = \{a_1, \ldots, a_s\}$ say, and for $1 \leq i \leq s$ let $N_i$ be the set of neighbours of $a_i$ in $A$.

Now take a graph consisting of $s+1$ isomorphic copies of $A \setminus S$, say $A_0, \ldots, A_s$, pairwise disjoint and with no edges between them. For $0 \leq i,j \leq s$, let the isomorphism from $A \setminus S$ to $A_i$ map $N_j$ to $N_{ij}$. Now add to this $3s^2$ new vertices, namely $x_{ij}, y_{ij}, z_{ij}$ for all $i, j$ with $1 \leq i, j \leq s$. Also add edges so that $x_{ij}, y_{ij}$ are both adjacent to every vertex in $N_0,i$, and $x_{ij}, z_{ij}$ are both adjacent to every vertex in $N_{ij}$, and $y_{ij}z_{ij}$ an edge, for $1 \leq i, j \leq s$. Let $G$ be the resulting graph, and let $T$ be the set

$$\{x_{ij}, y_{ij} : 1 \leq i, j \leq s\}.$$ 

We say that $(G,T)$ is obtained by composing $(A,S)$ with itself.

To define $SP_k$ let $SP_1$ be the complete graph $K_2$, and let $T_1 \subseteq V(SP_1)$ with $|T_1| = 1$. Inductively let $(SP_{k+1}, T_{k+1})$ be obtained by composing $(SP_k, T_k)$ with itself. It is easy to check that $SP_k$ has no triangles, and for every colouring of $SP_k$ with any number of colours, some vertex in $T_k$ has neighbours of $k$ different colours, and in particular $\chi(SP_k) \geq k + 1$. Moreover, there are graphs $H$ such that no subdivision of $H$ appear as an induced subgraph of any $SP_k$, as discussed in the previous section. $SP_k$ is the only construction known to the authors with this property. Indeed, the following very wild statement might be true as far as we know:

2.1 Conjecture: For all $m, i, \nu \geq 0$ there exists $n$ such that if $G$ has $\omega(G) \leq \nu$ and $\chi(G) > n$, then either some $(\geq 1)$-subdivision of $K_{m,i}$ appears in $G$ as an induced subgraph, or $SP_1$ appears in $G$ as an induced subgraph.
We have little faith in this conjecture; indeed we cannot prove it even for graphs $G$ that are themselves induced subgraphs of some $SP_k$. We could make it more plausible by weakening it to: “For all $i, \nu \geq 0$ there exists $n$ such that if $G$ has $\omega(G) \leq \nu$ and $\chi(G) > n$, then some subdivision of $SP_i$ appears in $G$ as an induced subgraph”, and indeed then we think it might well be true; but first we should disprove the stronger form.

3 Two routing lemmas

If $X, Y$ are subsets of the vertex set of a graph $G$, we say

- $X$ is complete to $Y$ if $X \cap Y = \emptyset$ and every vertex in $X$ is adjacent to every vertex in $Y$;
- $X$ is anticomplete to $Y$ if $X \cap Y = \emptyset$ and every vertex in $X$ is nonadjacent to every vertex in $Y$; and
- $X$ covers $Y$ if $X \cap Y = \emptyset$ and every vertex in $Y$ has a neighbour in $X$.

(If $X = \{v\}$ we say $v$ is complete to $Y$ instead of $\{v\}$, and so on.)

Throughout the paper, we will be applying various forms of Ramsey’s theorem. Here is one that contains all that we need.

3.1 For all integers $k, n, \alpha, \beta \geq 0$ there exists $R(k, n, \alpha, \beta) \geq n$ with the following property. Let $A, B$ be disjoint sets, both of cardinality at least $R(k, n, \alpha, \beta)$. Let $E$ be the set of all sets $X \subseteq A \cup B$ with $|X \cap A| = \alpha$ and $|X \cap B| = \beta$. If we partition $E$ into $k$ subsets, then there exist $A' \subseteq A$ and $B' \subseteq B$ with $|A'| = |B'| = n$ such that all the sets $X \in E$ with $X \subseteq A' \cup B'$ belong to the same subset.

Before we begin the main proofs, we prove two lemmas which will be applied later. We are trying to prove that certain graphs $G$ with bounded clique number contain a subdivision of some fixed graph $H$ as an induced subgraph. This is true if $G$ has an induced subgraph which is a proper subdivision of $K_{\mu,\mu}$ for appropriate $\mu$; and so we might as well confine ourselves to graphs $G$ that do not contain (as an induced subgraph) any proper subdivision of $K_{\mu,\mu}$, for some fixed $\mu$. This is a little more than we actually need. For integers $\lambda \geq 2$ and $\mu, \nu \geq 0$, let us say that $G$ is $(\lambda, \mu, \nu)$-restricted if $\omega(G) \leq \nu$, and no induced subgraph of $G$ is a proper $(\leq \lambda)$-subdivision of $K_{\mu, \mu}$.

Let $G, H$ be graphs. An impression of $H$ in $G$ is a map $\eta$ with domain $V(H) \cup E(H)$, such that:

- $\eta(v) \in V(G)$ for each $v \in V(H)$;
- for all distinct $u, v \in V(H)$, $\eta(u) \neq \eta(v)$ and $\eta(u), \eta(v)$ are nonadjacent in $G$;
- for every edge $e = uv$ of $H$, $\eta(e)$ is a path of $G$ with ends $\eta(u), \eta(v)$;
- if $e, f \in E(H)$ have no common end then $V(\eta(e))$ is anticomplete to $V(\eta(f))$.

The order of an impression $\eta$ is the maximum length of the paths $\eta(e)$ ($e \in E(H)$).

Our first lemma is:

3.2 For all $\lambda \geq 1$ and $\mu, \nu \geq 0$, there exists $m$ such that if $G$ is $(\lambda, \mu, \nu)$-restricted then there is no impression of $K_{m, m}$ in $G$ of order at most $\lambda + 1$.  

5
Proof. We proceed by induction on \( \lambda \). If \( \lambda > 1 \) choose \( m_4 \) such that the theorem is satisfied with \( \lambda \) replaced by \( \lambda - 1 \) and \( m \) by \( m_4 \), and if \( \lambda = 1 \) let \( m_4 = 0 \). Let
\[
\begin{align*}
m_3 &= \max(m_4 + 1, \mu, \nu + 2) \\
m_2 &= R(3^{3^2}, m_3, 2, 1) \\
m_1 &= R(3^{3^2}, m_2, 1, 2) \\
m &= R(\lambda, m_1, 1, 1).
\end{align*}
\]
We claim that \( m \) satisfies the theorem. For suppose that \( \eta \) is an impression of \( K_{m,m} \) in \( G \) of order at most \( \lambda + 1 \).

(1) \( \{ \eta(v) : v \in V(H) \} \) is a stable set of \( G \), and if \( e \in E(H) \) and \( v \in V(H) \) is not incident with \( e \), then \( \eta(v) \) does not belong to \( \eta(e) \), and has no neighbours in \( V(\eta(e)) \).

The first is immediate from the definition of impression. For the second, if \( e \in E(H) \) and \( v \in V(H) \) not incident with \( e \), then there is an edge \( f \) of \( H \) incident with \( v \) and with no common end with \( e \), and since \( V(\eta(e)) \) is anticomplete to \( V(\eta(f)) \), it follows in particular that \( \eta(v) \) does not belong to \( \eta(e) \), and has no neighbours in \( V(\eta(e)) \). This proves (1).

Also we might as well assume that each path \( \eta(e) \) is an induced path in \( G \). Let \( (A, B) \) be a bipartition of \( H = K_{m,m} \). There are only \( \lambda \) possibilities for the length of each path \( \eta(e) \) (\( e \in E(H) \)); and so by 3.1, there exist \( A_1 \subseteq A \) and \( B_1 \subseteq B \) with \( |A_1| = |B_1| = m_1 \) such that the paths \( \eta(ab) \) all have the same length, for all \( a \in A_1 \) and \( b \in B_1 \). Let this common length be \( \ell \); thus \( 2 \leq \ell \leq \lambda + 1 \). Let us number the vertices of each path \( \eta(ab) \) (\( a \in A_1, b \in B_1 \)) as \( p_{ab0}, p_{ab1}, \ldots, p_{abl} \) in order, where \( p_{ab0} = \eta(a) \) and \( p_{abl} = \eta(b) \).

Take an ordering of \( B \), denoted by \( < \). For each \( a \in A \) and all \( b, b' \in B \) with \( b < b' \), let us say the first pattern of \( (a, b, b') \) is the set of all pairs \( (i, j) \) with \( 1 \leq i, j \leq \ell - 1 \) such that \( p_{abi} = p_{abj} \); and the second pattern of \( (a, b, b') \) is the set of all pairs \( (i, j) \) with \( 1 \leq i, j \leq \ell - 1 \) such that \( p_{abi}, p_{abj} \) are distinct and adjacent in \( G \). There are only \( 3^{3^2} \) possibilities for the first and second patterns; so by 3.1 there exist \( A_2 \subseteq A_1 \) and \( B_2 \subseteq B_1 \) with \( |A_2| = |B_2| = m_2 \), such that all the triples \( (a, b, b') \) (for \( a \in A_2 \) and \( b, b' \in B_2 \) with \( b < b' \)) have the same first patterns and they all have the same second patterns. Let these patterns be \( \Pi_1, \Pi_2 \) say.

Similarly, by exchanging \( A, B \), choosing an ordering \( < \) of \( A_2 \) and repeating the argument, we deduce that there exist \( A_3 \subseteq A_2 \) and \( B_3 \subseteq B_2 \) with \( |A_3| = |B_3| = m_3 \), and sets \( \Pi_3, \Pi_4 \subseteq \{1, \ldots, \ell - 1\}^2 \) such that for all \( a, a' \in A_3 \) with \( a < a' \) and \( b \in B_4, p_{abi} = p_{a'bj} \) if and only if \( (i, j) \in \Pi_3 \), and \( p_{abi}, p_{a'bj} \) are different and adjacent if and only if \( (i, j) \in \Pi_4 \).

(2) \( \Pi_1, \Pi_2 = \emptyset \).

For suppose that there exists \( (i, j) \in \Pi_1 \cup \Pi_2 \). By reversing the order on \( B \) if necessary, we may assume that \( i \leq j \). Choose \( b_0 \in B_3 \), minimal under the ordering of \( B \). For each \( a \in A_3 \) and \( b \in B_3 \setminus \{b_0\} \), let
\[
Q(ab) = \{p_{abj}, p_{ab(j+1)}, \ldots, p_{abl}\}.
\]
Since \( (i, j) \in \Pi_1 \cup \Pi_2 \), it follows that for each \( a \in A_3 \) and \( b \in B_3 \setminus \{b_0\} \), there is a path \( P_{ab} \) of \( G \) with ends \( p_{ab0}, b \) and with vertex set a subset of \( \{p_{ab0}\} \cup Q(ab) \). For each \( b \in B_3 \setminus \{b_0\} \) let
\( \eta'(b) = \eta(b) \); for each \( a \in A_3 \), let \( \eta'(a) = p_{abq_i} \); and for every edge \( ab \) of \( H = K_{m,m} \) with \( a \in A_3 \) and \( b \in B_3 \setminus \{b_0\} \), let \( \eta'(ab) = P_{ab} \). We claim that \( \eta' \) is an impression of \( K_{m_3+1,m_3} \) in \( G \). To see this, note first that the vertices \( \eta'(a) (a \in A_3) \) are all distinct; for choose \( b \in B_3 \setminus \{b_0\} \), and let \( a, a' \in A_3 \) be distinct. Then \( p_{abq_i} \) is equal or adjacent to \( p_{abj} \), but \( p_{abq_i} \) is different from and nonadjacent to \( p_{abj} \) since \( V(\eta'(ab)) \), \( V(\eta(ab)) \) are anticomplete, from the definition of an impression. Consequently \( p_{abq_i} \) is different from \( p_{abq_{i'}} \). If \( (i, i) \in \Pi_4 \), then all the vertices \( p_{abq_i} (a \in A_3) \) are pairwise adjacent, contradicting that \( \omega(G) \leq \nu \); so \( (i, i) \notin \Pi_4 \), and the vertices \( \eta'(a) (a \in A_3) \) are pairwise nonadjacent. Also for each \( a \in A_3 \) and \( b \in B_3 \setminus \{b_0\} \), \( \eta'(a) \) is different from and nonadjacent to \( \eta'(b) \) by (1). Thus the first three conditions for an impression are satisfied. For the final condition, we must check that if \( a, a' \in A_3 \) are distinct and \( b, b' \in B_3 \setminus \{b_0\} \) are distinct, then \( V(P_{ab}) \) is anticomplete to \( V(P_{a'b'}) \). We recall that \( V(P_{ab}) \subseteq \{p_{abq_i}\} \cup Q(ab) \), where \( Q(ab) \) is a subset of the vertex set of \( \eta(ab) \), and \( V(P_{a'b'}) \subseteq \{p_{abq_{i'}}\} \cup Q(a'b') \). We have seen that \( p_{abq_i}, p_{abq_{i'}} \) are distinct and nonadjacent, so, exchanging \( a, a' \) and \( b, b' \) if necessary, it suffices to show that \( V(P_{ab}) \) is anticomplete to \( Q(a'b') \). But \( V(P_{ab}) \) is a subset of \( V(\eta(ab)) \cup V(\eta(ab)) \), and both the latter sets are anticomplete to \( V(\eta(a'b')) \supseteq Q(a'b') \). This proves that \( \eta' \) is an impression as claimed.

Since \( m_3 - 1 \geq m_4 \), the inductive hypothesis on \( \lambda \) implies that the order of \( \eta' \) is at least \( \lambda + 1 \). But its order is at most \( \ell - j + 1 \) if \( (i, j) \in \Pi_2 \), and at most \( \ell - j \) if \( (i, j) \in \Pi_1 \). Since \( \ell \leq \lambda + 1 \) and \( j \geq 1 \), we deduce that \( j = 1 \), and \( \ell = \lambda + 1 \); and so \( i = 1 \), since \( i \leq j \), and \( (1, 1) \in \Pi_2 \). Choose \( a \in A_3 \); then all the vertices \( p_{abq_i} (b \in B_3 \setminus \{b_0\}) \) are distinct and pairwise adjacent, contradicting that \( \omega(G) \leq \nu \). This proves (2).

Similarly \( \Pi_3, \Pi_4 = \emptyset \). But then \( G \) contains an \( \ell \)-subdivision of \( K_{m_3,m_3} \), contradicting that \( G \) is \((\lambda, \mu, \nu)\)-restricted. This proves 3.2.

The second lemma is:

**3.3** For all \( \mu, \nu \geq 0 \), there exists \( m \) with the following property. Let \( G \) be \((1, \mu, \nu)\)-restricted, and let \( X \subseteq V(G) \) with \(|X| \geq m \). Then there exist distinct nonadjacent \( x, x' \in X \) such that every vertex of \( G \) adjacent to both \( x, x' \) has at least one more neighbour in \( X \).

**Proof.** Choose \( m_4 \) such that 3.2 holds with \( m \) replaced by \( m_4 \). Let

\[
\begin{align*}
m_3 &= \max(m_4, \nu + 1); \\
m_2 &= R(4, m_3, 2, 2); \\
m_1 &= 2m_2; \\
m &= R(2, m_1, 2, 0).
\end{align*}
\]

We claim that \( m \) satisfies the theorem. For suppose that \( G, X \) are as in the theorem, and for all distinct nonadjacent \( x, x' \in X \) there exists \( w(x, x') \) adjacent to both \( x, x' \) and nonadjacent to all other vertices in \( X \). Since \( \omega(G) \leq \nu < m_1 \), there is a stable subset \( X_1 \) of \( X \) with \(|X_1| = m_1 \), by 3.1. It follows that all the vertices \( w(x, x') (x, x' \in M_1, x \neq x') \) are distinct from one another and distinct from the vertices in \( M_1 \). Choose two disjoint subsets \( A_2, B_2 \) of \( X_1 \), both of cardinality \( m_2 \). Take an ordering of \( A_2 \) and of \( B_2 \), both denoted by \( \prec \). Let \( E \) be the set of all quadruples \((a, a', b, b') \) such that \( a, a' \in A, a < a' \), and \( b, b' \in B \) and \( b < b' \). For all \((a, a', b, b') \in E \), we say the first pattern of \((a, a', b, b') \) is 1 or 0 depending whether \( w(a, b), w(a', b') \) are adjacent or not; and the second pattern
is 1 or 0 depending whether \(w(a, b'), w(a', b)\) are adjacent or not. There are four possible choices of first and second pattern; so by 3.1 there exist \(A_3 \subseteq A_2\) and \(B_3 \subseteq B_2\) with \(|A_3| = |B_3| = m_3\), such that, if \(E_3\) denotes the set of \((a, a', b, b') \in E\) with \(a, a' \in A_3\) and \(b, b' \in B_3\), then

- either \(w(a, b), w(a', b')\) are adjacent for all \((a, a', b, b') \in E_3\), or \(w(a, b), w(a', b')\) are nonadjacent for all \((a, a', b, b') \in E_3\); and
- either \(w(a, b'), w(a', b)\) are adjacent for all \((a, a', b, b') \in E_3\), or \(w(a, b'), w(a', b)\) are nonadjacent for all \((a, a', b, b') \in E_3\).

Suppose that \(w(a, b), w(a', b')\) are adjacent for all \((a, a', b, b') \in E_3\). Choose

\[
\begin{align*}
  a_1 < a_2 < \cdots < a_{\nu + 1} & \in A_3 \\
  b_1 < b_2 < \cdots < b_{\nu + 1} & \in B_3
\end{align*}
\]

(this is possible since \(m_3 \geq \nu + 1\)); then the vertices \(w(a_1, b_1), w(a_2, b_2), \ldots, w(a_{\nu + 1}, b_{\nu + 1})\) are pairwise adjacent, contradicting that \(\omega(G) \leq \nu\). So the nonadjacency alternative holds in the first bullet above, and similarly nonadjacency holds in the second bullet. Let \((A', B')\) be a bipartition of \(K_{m_3, m_3}\), and choose \(\eta\) mapping \(A'\) onto \(A\) and \(B'\) onto \(B\); and for all \(a' \in A'\) and \(b' \in B'\), let \(\eta(a'b')\) be the path of \(G\) with vertex set \(\{a, w(a, b), b\}\) where \(a = \eta(a')\) and \(b = \eta(b')\). Then \(\eta\) is an impression of \(K_{m_3, m_3}\) in \(G\), of order 2, and the result follows from 3.2. This proves 3.3.

4 Multicovers

A **levelling** in a graph \(G\) is a sequence of pairwise disjoint subsets \((L_0, L_1, \ldots, L_k)\) of \(V(G)\) such that

- \(|L_0| = 1\);
- for \(1 \leq i \leq k\), \(L_{i-1}\) covers \(L_i\); and
- for \(0 \leq i < j \leq k\), if \(j > i + 1\) then \(L_i\) is anticomplete to \(L_j\).

If \(L = (L_0, L_1, \ldots, L_k)\) is a levelling, \(L_k\) is called the base of \(L\), and the vertex in \(L_0\) is the apex of \(L\), and \(L_0 \cup \cdots \cup L_k\) is the union of \(L\), denoted by \(V(L)\). If \(L = (L_0, L_1, \ldots, L_k)\) and \(L' = (L'_0, L'_1, \ldots, L'_k)\) are levellings, we say that \(L'\) is contained in \(L\) if \(L'_i \subseteq L_i\) for \(0 \leq i \leq k\).

Let \(L = (L_0, L_1, \ldots, L_k)\) be a levelling in \(G\) with \(k \geq 1\), and let \(C \subseteq V(G) \setminus V(L)\). We say that \(L\) is a **k-cover** for \(C\) if \(L_k\) covers \(C\), and \(L_0, \ldots, L_{k-1}\) are anticomplete to \(C\). Let \(L = (L_0, \ldots, L_k)\) be a k-cover of \(C\), with apex \(x\) say. If \(z \in C\), then \(z\) has a neighbour in \(L_k\), and that vertex has a neighbour in \(L_{k-1}\), and so on; and hence there is a path between \(z\) and \(x\) of length \(k + 1\), with exactly one vertex in each of \(L_0, \ldots, L_k\). Moreover, this path is induced; we call such a path an \(L\)-radius for \(z\).

For \(C \subseteq V(G)\), a k-multicover for \(C\) in \(G\) is a family \(\mathcal{M} = (\mathcal{L}_i : i \in I)\), where \(I\) is a set of integers, such that

- for \(1 \leq i \leq m\), \(\mathcal{L}_i\) is a k-cover for \(C\);
- for \(1 \leq i < j \leq m\), \(V(\mathcal{L}_i)\) is disjoint from \(V(\mathcal{L}_j)\).
• for all \(i, j \in I\) with \(i < j\), every vertex in \(V(L_i)\) with a neighbour in \(V(L_j)\) belongs to the base of \(L_i\).

We denote the union of the sets \(V(L_i)\) \((i \in I)\) by \(V(M)\). We call \(|I|\) the magnitude of the multicover. Let \(M = (L_i : i \in I)\) and \(M' = (L'_i : i \in I')\) be \(k\)-multicovers in \(G\) for \(C\) and for \(C'\), respectively, where \(C' \subseteq C\). If \(I' \subseteq I\), and \(L'_i\) is contained in \(L_i\) for each \(i \in I'\), we say that \(M'\) is contained in \(M\).

Let \(M = (L_i : i \in I)\) be a \(k\)-multicover for \(C\) in \(G\). Let \(z \in V(G) \setminus (V(M) \cup C)\), and for each \(i \in I\) let \(S_i\) be an induced path of \(G\) between \(z\) and the apex \(x_i\) say of \(L_i\), such that

- \(z\) has no neighbours in \(V(M) \cup C\);
- for each \(i \in I\), \(V(S_i) \cap (V(M) \cup C) = \{x_i\}\); and
- for each \(i \in I\), every vertex in \(V(M) \cup C\) with a neighbour in \(V(S_i) \setminus \{x_i\}\) belongs to \(V(L_i)\).

(We do not require the paths \(S_i\) to be pairwise internally disjoint; they may intersect one another arbitrarily.) We say that the family \((S_i : i \in I)\) is a tick on \((M, C)\), and \(z\) is its head, and its order is the maximum length of the paths \(S_i\) \((i \in I)\). We need to prove the following.

4.1 For all \(k \geq 2\) and \(\mu, \nu, \tau, m', c' \geq 0\) there exist \(m, c \geq 0\) with the following property. Let \(G\) be a \((1, \mu, \nu)\)-restricted graph such that \(\chi^k(G) \leq \tau\). Let \(C \subseteq V(G)\) with \(\chi(C) > c\), and let \(M\) be a \(k\)-multicover for \(C\) with magnitude \(m\). Then there exist \(C' \subseteq C\) with \(\chi(C') \geq c'\), and a \(k\)-multicover \(M'\) for \(C'\) contained in \(M\) with magnitude \(m'\), and a tick \((S_i : i \in I)\) on \((M', C')\) of order at most \(k + 4\), such that \(V(S_i) \subseteq V(M)\) for each \(i \in I\).

The proof breaks into two cases, depending whether \(k = 2\) or not. In this section we handle the easier case \(k \geq 3\), and postpone \(k = 2\) until the next section. When \(k \geq 3\), a stronger statement holds, the following:

4.2 For all \(k \geq 3\) and \(\tau, m, c' \geq 0\) there exists \(c \geq 0\) with the following property. Let \(G\) be a graph such that \(\chi^k(G) \leq \tau\). Let \(C \subseteq V(G)\) with \(\chi(C) > c\), and let \(M = (L_i : i \in I)\) be a \(k\)-multicover for \(C\) with \(|I| = m\). Then there exist \(C' \subseteq C\) with \(\chi(C') \geq c'\), and a \(k\)-multicover \(M'\) for \(C'\) contained in \(M\) with magnitude \(m\), and a tick \((S_i : i \in I)\) on \((M', C')\) with head \(z \in C \setminus C'\), such that for each \(i \in I\), \(S_i\) has length \(k + 1\), and \(V(S_i) \subseteq V(L_i) \cup \{z\}\) (and so the paths \(S_i\) \((i \in I)\) are pairwise disjoint except for \(z\)).

Proof. Let \(c = c' + (mk + 1)\tau\), and let \(G, C\) and \(M = (L_i : i \in I)\) be as in the theorem. Let \(x_i\) be the apex of \(L_i\) for each \(i \in I\), and let \(X = \{x_i : i \in I\}\). For each \(i \in I\), let \(C_i\) be the set of vertices in \(C\) with distance at most \(k\) from \(x_i\) in \(G\). Then by hypothesis, \(\chi(C_i) \leq \tau\); let \(D\) be the set of vertices in \(C\) that do not belong to the union of the sets \(C_i\) \((i \in I)\). It follows that \(\chi(D) > c - m\tau\). Since \(c \geq m\tau\), there exists \(z \in D\); choose some such \(z\). For each \(i \in I\) let \(S_i\) be some \(L_i\)-radius for \(z\).

(1) For all distinct \(i, i' \in I\), \(x_{i'}\) has no neighbours in \(V(S_i)\).

Suppose that some \(x_{i'}\) is adjacent to a vertex in \(S_i\). Since \(S_i\) has length \(k + 1\), and the distance from \(x_{i'}\) to \(z\) is at least \(k + 1\) (because \(z \notin C_{i'}\)), and \(X\) is stable, it follows that \(x_{i'}\) is adjacent to the neighbour of \(x_i\) in \(S_i\); but this contradicts that \(M\) is a multicolor, since \(k \geq 3\). This proves (1).
Let $S$ be the union of the sets $V(S_i)$ ($i \in I$). Thus $|S| = mk + 1$. Let $C'$ be the set of vertices in $C$ with distance at least $k + 1$ in $G$ from every vertex in $S$. Since $X \subseteq S$ it follows that $C' \subseteq D$, and $z \in D \setminus C'$, and $\chi(C') > c - (mk + 1)\tau = c'$. For each $j \in I$, let $L_j = (L_{0j}, \ldots, L_{kj})$ say, and for $0 \leq i \leq k$ let $L_{ij}$ be the set of vertices $v \in L_{ij}$ such that some $L_j$-radius contains both $v$ and a vertex in $C$; and let $L_j' = (L_{0j}', \ldots, L_{kj}')$. Then $L_j'$ is a $k$-covering for $C'$; let $\mathcal{M}' = (L_j' : j \in I)$, and then $\mathcal{M}'$ is a $k$-multicover for $C'$ contained in $\mathcal{M}$. We claim that it satisfies the theorem. Certainly $z \in C \setminus C'$.

(2) $V(S_i) \cap V(\mathcal{M}') = \{x_i\}$ for each $i \in I$.

For suppose that $u \in V(S_j) \cap V(\mathcal{M}')$, and choose $j' \in I$ such that $u \in V(L_{ij}')$. Since $V(S_j) \subseteq V(L_j)$ and $V(L_{ij}') \subseteq V(L_{ij'})$, it follows that $V(L_j')$ is not disjoint from $V(L_{ij'})$, and so $j' = j$. Since $u \in V(L_{ij'})$, there exists $i$ with $0 \leq i \leq k$ such that $u \in L_{ij}'$; and so the distance in $G$ between $u$ and some vertex in $C'$ is at most $k + 1 - i$. But from the definition of $C'$, since $u \in S$ it follows that this distance is at least $k + 1$, and so $i = 0$, that is, $u = x_j$. This proves (2).

(3) For each $j \in I$, if some $u \in V(S_j)$ is adjacent to some $v \in V(\mathcal{M}') \cup C'$ then $v \in V(L_{ij}')$.

Assume that $u \in V(S_j)$ and $v \in V(\mathcal{M}') \cup C'$ are adjacent. Since $u \in S$ and so has distance at least $k + 1$ from every vertex in $C'$, it follows that $v \notin C'$, and so $v \in V(L_{ij}')$ for some $j' \in I$. Choose $i$ such that $v \in L_{ij}'$; then the distance in $G$ between $u$ and some vertex in $C'$ is at most $k + 1 - i$, and so the distance between $u$ and some vertex in $C'$ is at most $k + 2 - i$. Since this distance is at least $k + 1$, it follows that $i \leq 1$, and so $v$ is equal to or adjacent to $x_{j'}$, and in either case $v$ does not belong to the base of $L_{ij'}$. If $u$ belongs to the base of $L_j$, then $u$ is adjacent to $z$ (because only one vertex in $S_j$ belongs to the base of $L_j$, namely the neighbour of $z$); and since $i \leq 1$, and therefore the distance between $u$ and $x_{j'}$ in $G$ is at most 2, it follows that the distance between $z$ and $x_{j'}$ is at most 3, contrary to the definition of $D$ (since $k \geq 3$). Thus $u$ does not belong to the base of $L_j$; and since $\mathcal{M}$ is a multicover, it follows that $j = j'$. This proves (3).

From (1), (2) and (3) it follows that $(S_i : i \in I)$ is a tick on $(\mathcal{M}', C')$. This proves 4.2.

## 5 Extracting ticks from 2-multicovers

In this section we prove 4.1 when $k = 2$. We will need the following lemma, proved in [5]:

5.1 Let $\mathcal{A}$ be a set of nonempty subsets of a finite set $V$, and let $k \geq 0$ be an integer. Then either:

- there exist $A_1, A_2 \in \mathcal{A}$ with $A_1 \cap A_2 = \emptyset$;
- there are $k$ distinct members $A_1, \ldots, A_k \in \mathcal{A}$, and for all $i, j$ with $1 \leq i < j \leq k$ an element $v_{ij} \in V$, such that for all $h, i, j \in \{1, \ldots, k\}$ with $i < j$, $v_{ij} \in A_h$ if and only if $h \in \{i, j\}$; or
- there exists $X \subseteq V$ with $|X| \leq 11(k + 4)^5$ such that $X \cap A \neq \emptyset$ for all $A \in \mathcal{A}$.

The idea of using 5.1 in this context is due to Bousquet and Thomassé [1]. We use it to prove the following.
5.2 For all $\mu, \nu \geq 0$, there exists $m \geq 0$ with the following property. Let $G$ be $(1, \mu, \nu)$-restricted, and let $X \subseteq V(G)$, such that every two vertices in $X$ have distance at most 2 in $G$. Then there exists $Y \subseteq V(G)$ with $|Y| \leq m$ such that every vertex in $X \setminus Y$ has a neighbour in $Y$.

**Proof.** Choose $k$ such that 3.3 holds with $m$ replaced by $k$, and let $m = 11(k+4)^5$. We claim that $m$ satisfies the theorem; for let $G, X$ be as in the theorem. For each $x \in X$, let $N[x]$ be the set of all vertices equal to or adjacent in $G$ to $x$, and let $A$ be the set of all vertices in $N[x]$. By hypothesis, no two vertices in $N[x]$ are adjacent. Suppose that there are $k$ distinct members $A_1, \ldots, A_k \in A$, and for all $i,j$ with $1 \leq i < j \leq k$ a vertex $v_{ij} \in V(G)$, such that for all $h, i, j \in \{1, \ldots, k\}$ with $i < j$, $v_{ij} \in A_h$ if and only if $h \in \{i,j\}$. For $1 \leq i \leq k$, let $A_i = N[x_i]$; then for all $i, j$ with $1 \leq i < j \leq k$, either $x_i, x_j$ are adjacent in $G$ or there is a vertex adjacent to $x_i$ and to $x_j$, and nonadjacent to all other vertices in $\{x_1, \ldots, x_k\}$. But this is impossible from the choice of $k$.

From 5.1 we deduce that there exists $Y \subseteq V$ with $|Y| \leq 11(k+4)^5 = m$ such that $Y \cap A \neq \emptyset$ for all $A \in A$. But then every vertex in $X$ either belongs to $Y$ or has a neighbour in $Y$. This proves 5.2. \qed

If $M = (\mathcal{L}_i : i \in I)$ is a 2-multicover of $C$, and $i, j \in I$ are distinct, and $z \in C$, let $P, Q$ be $\mathcal{L}_i$- and $\mathcal{L}_j$-radii for $z$ respectively; then $P \cup Q$ is a path of $G$ (not necessarily induced), and we call such a path an $(\mathcal{L}_i, \mathcal{L}_j)$-diameter. We need another lemma.

5.3 For all $\mu, \nu, \tau, c' \geq 0$ and $m > 0$ there exist $c \geq 0$ with the following property. Let $G$ be a $(1, \mu, \nu)$-restricted graph such that $\chi^2(G) \leq \tau$. Let $C \subseteq V(G)$ with $\chi(C) > c$, and let $M = (\mathcal{L}_i : i \in I)$ be a 2-multicover for $C$ with $|I| = m$. Let $x_i$ be the apex of $\mathcal{L}_i$ for $i \in I$. Let $k \in I$ be maximum. For each $g \in I \setminus \{k\}$, there exist

- a subset $I' \subseteq I \setminus \{k\}$ with $|I'| \geq m/2$ and with $\{i \in I : i \leq g\} \subseteq I'$;
- a subset $C' \subseteq C$ with $\chi(C') > c'$;
- for each $i \in I'$, a 2-cover $\mathcal{L}_i'$ for $C'$ contained in $\mathcal{L}_i$; and
- an $(\mathcal{L}_g, \mathcal{L}_k)$-diameter $S$, such that $V(S)$ is anticomplete to $C'$, and $V(S)$ is anticomplete to $V(\mathcal{L}_i')$ for each $i \in I' \setminus \{g\}$, and $V(S) \cap V(\mathcal{L}_g) = \{x_g\}$.

**Proof.** Choose $m_0$ such that 5.2 holds with $m$ replaced by $m_0$. Let $c = \max(m_0 \tau, 12 \tau + c'/2^{m+1})$. We claim that $c$ satisfies the theorem. For let $G, C, M = (\mathcal{L}_i : i \in I), k, g$ be as in the theorem, where $\mathcal{L}_i = (\{x_i\}, A_i, B_i)$ for each $i \in I$, say. We may assume that every vertex in $B_g$ has a neighbour in $C$, because any other vertex of $B_g$ can be deleted. Suppose that $Y \subseteq V(G)$, and every vertex in $B_g \setminus Y$ has a neighbour in $Y$. Then every vertex in $C$ has distance at most two from a vertex in $Y$, and so $\chi(C) \leq \lfloor Y \rfloor \tau$; and since $\chi(C) > c$, it follows that $|Y| > c\tau^{-1} > m_0$. From 5.2, there exist $y_1, y_2 \in B_g$ with distance at least three in $G$. Choose $z_1, z_2 \in C$ adjacent to $y_1, y_2$ respectively. Let $S_1$ be an $(\mathcal{L}_g, \mathcal{L}_k)$-diameter containing $y_1$ and $z_1$, and choose $S_2$ for $y_2, z_2$ similarly. The union of $S_1$ and $S_2$ has at most 12 vertices, and so the set of vertices in $C$ with distance at most two from a vertex in $S_1 \cup S_2$ has chromatic number at most $12 \tau$. Consequently there exists $C_1 \subseteq C$ with $\chi(C_1) > c - 12 \tau$ such that every vertex in $C_1$ has distance at least three from every vertex in $S_1 \cup S_2$. For $1 \leq i \leq g$, let $\mathcal{L}_i'$ be the levelling $(\{x_i\}, A_i', B_i')$, where $B_i'$ is the set of vertices in $B_i$ with a neighbour in $C_1$, and $A_i'$ is the set of vertices in $A_i$ with a neighbour in $B_i'$. Then $V(S_1 \cup S_2) \cap V(\mathcal{L}_g') = \{x_g\}$, because
every vertex in $C_1$ has distance at least three from $S_1 \cup S_2$. Also $V(S_1 \cup S_2)$ is anticomplete to $V(L'_i)$ if $i < g$, since every vertex in $V(L_i)$ with a neighbour in $S_1 \cup S_2$ belongs to $B_i$ (from the definition of a 2-multicover) and hence does not belong to $B'_i$ (because vertices in $B'_i$ have neighbours in $C_1$ and therefore have no neighbours in $S_1 \cup S_2$).

Now we shall choose one of $S_1$, $S_2$ to satisfy the other requirements of the theorem. For each $j \in I \setminus \{k\}$ with $j > g$ and each $v \in C_1$, let $P_{jv}$ be an $L_j$-radius for $v$. For $x \in C_1$ for the moment. Now $P_{jv}$ has length three, let its vertices be $x_j, a_{jv}, b_{jv} v$ in order. Since $v \in C_1$ and therefore has distance three from every vertex in $S_1 \cup S_2$, it follows that $b_{jv}$ has no neighbour in $S_1 \cup S_2$; but $a_{jv}$ might have neighbours in $S_1 \cup S_2$. From the definition of a multicover, every neighbour of $a_{jv}$ in $S_1 \cup S_2$ is one of $y_1, y_2$; and since $y_1, y_2$ have distance at least three in $G$, $a_{jv}$ is not adjacent to them both. Consequently $V(P_{jv})$ is anticomplete to at least one of $S_1, S_2$. Choose $I_v \subseteq I \setminus \{k\}$ including $\{i \in I : i \leq g\}$, with $|I_v| \geq m/2$, such that for one of $S_1, S_2$ (say $S_v$), each of the paths $P_{jv}$ ($j \in I_v, j > g$) is anticomplete to $S_v$. There are only $2^{m+1}$ possibilities for the pair $(S_v, I_v)$; and so there exists $C' \subseteq C_1$ with $\chi(C') \geq \chi(C_1)2^{-m-1} > c'$, and one of $S_1, S_2$, say $S$, and a set $I'$, such that $S_v = S$ and $I_v = I'$ for all $v \in C'$. For each $j \in I \setminus \{k\}$ with $j > g$, let $L'_j$ be the levelling $(\{x_j\}, A'_j, B'_j)$, where $A'_j = \{a_{jv} : v \in C'\}$ and $B'_j = \{b_{jv} : v \in C'\}$. Then the theorem is satisfied. This proves 5.3.

We deduce:

**5.4** For all $\mu, \nu, \tau, c' > 0$, and $t > 0$, and $m \geq t2^t$, there exist $c \geq 0$ with the following property. Let $G$ be a $(\mu, \nu)$-restricted graph such that $\chi^2(G) \leq \tau$. Let $C \subseteq V(G)$ with $\chi(C) > c$, and let $\mathcal{M} = (L_i : i \in I)$ be a 2-multicover for $C$ with $|I| = m$. Let $k \in I$ be maximum. Then there exist

- a subset $I' \subseteq I \setminus \{k\}$ with $|I'| \geq m2^{-t}$; $I' = \{i_1, \ldots, i_n\}$ say, where $i_1 < i_2 < \cdots < i_n$;
- a subset $C' \subseteq C$ with $\chi(C') > c'$;
- for each $i \in I'$, a 2-cover $L'_i$ for $C'$, contained in $L_i$;
- for each $i \in \{i_1, \ldots, i_n\}$, an $(L_i, L_k)$-diameter $S_i$, such that $V(S_i)$ is anticomplete to $C'$, and $V(S_i) \cap V(L'_j)$ for all $j \in I' \setminus \{i\}$, and $V(S_i) \cap V(L'_i) = \{x_i\}$.

**Proof.** We assume first that $t = 1$. Choose $c$ such that 5.3 is satisfied. Choose $g \in I$, minimum; then the result follows from 5.3. Thus the result holds if $t = 1$.

We fix $\mu, \nu, \tau, m$, and proceed by induction on $t$ (assuming $m \geq t2^t$). Thus we assume that $t > 1$ and the result holds with $t$ replaced by $t - 1$. Choose $c''$ such that 5.3 is satisfied with $c$ replaced by $c''$ (and the given value of $m$). Let $c$ have the value that satisfies the theorem with $t, c'$ replaced by $t - 1, c''$; we claim that $c$ satisfies the theorem.

For let $G, C$ and $\mathcal{M} = (L_i : i \in I), k$ be as in the theorem, where $|I| = m \geq t2^t$. From the inductive hypothesis, there exist

- a subset $I'' \subseteq I \setminus \{k\}$ with $|I''| \geq m2^{t-1}$; $I'' = \{i_1, \ldots, i_n\}$ say, where $i_1 < i_2 < \cdots < i_n$;
- a subset $C'' \subseteq C$ with $\chi(C'') > c''$;
- for each $i \in I''$, a 2-cover $L''_i$ for $C''$, contained in $L_i$;

12
for each $i \in \{i_1, \ldots, i_t\}$, an $(\mathcal{L}_i, \mathcal{L}_k)$-diameter $S_i$, such that $V(S_i)$ is anticomplete to $C''$, and $V(S_i)$ is anticomplete to $V(\mathcal{L}_i'')$ for all $j \in I'' \setminus \{i\}$, and $V(S_i) \cap V(\mathcal{L}_i'') = \{x_i\}$.

Let $\mathcal{L}_k'' = \mathcal{L}_k$. Thus $\mathcal{M}'' = (\mathcal{L}_i'' : i \in I'' \cup \{k\})$ is a 2-multicover of $C''$, contained in $\mathcal{M}$. Also $n \geq 2t$, since $n \geq 2t^{1-t}$ and $m \geq t2^t$. From 5.3 applied to $\mathcal{M}''$ taking $g = i_t$, we deduce that there exist

- a subset $I' \subseteq I''$ with $|I'| \geq (|I''| + 1)/2 \geq m2^{-t}$ and with $\{i_1, \ldots, i_t\} \subseteq I'$;
- a subset $C' \subseteq C''$ with $\chi(C') > c'$;
- for each $i \in I'$, a 2-cover $\mathcal{L}_i'$ for $C'$ contained in $\mathcal{L}_i''$;
- an $(\mathcal{L}_i'', \mathcal{L}_k'')$-diameter $S_{i_t}$ (which is therefore also an $(\mathcal{L}_i, \mathcal{L}_k)$-diameter), such that $V(S_{i_t})$ is anticomplete to $C'$, and $V(S_{i_t})$ is anticomplete to $V(\mathcal{L}_i')$ for all $i \in I' \setminus \{i_t\}$, and $V(S_{i_t}) \cap V(\mathcal{L}_i'_t) = \{x_{i_t}\}$.

But then $I', C', \mathcal{L}_i' (i \in I')$, and the paths $S_i (i \in \{i_1, \ldots, i_t\})$ satisfy the theorem. This proves 5.4.

Now we prove the main result of this section, the case of 4.1 for 2-multicovers:

5.5 For all $\mu, \nu, \tau, c' \geq 0$ and $m' > 0$ there exist $m, c \geq 0$ with the following property. Let $G$ be a $(1, \mu, \nu)$-restricted graph such that $\chi^2(G) \leq \tau$. Let $C \subseteq V(G)$ with $\chi(C) > c$, and let $\mathcal{M}$ be a 2-multicover for $C$, with magnitude $m$. Then there exist $C' \subseteq C$ with $\chi(C') > c'$, and a 2-multicover $\mathcal{M}'$ for $C'$ contained in $\mathcal{M}$ with magnitude $m'$, and a tick $(S_i : i \in I)$ on $(\mathcal{M}', C')$ of order at most 6, such that $V(S_i) \subseteq V(\mathcal{M})$ for each $i \in I$.

**Proof.** Let $m = m'2^{m''}$ and let $c$ satisfy 5.4 with this choice of $m$. We claim that $m, c$ satisfy the theorem. For let $G, C$ and $\mathcal{M} = (\mathcal{L}_i : i \in I)$ be as in the theorem. For each $i \in I$, let $\bar{\mathcal{L}}_i = (\{x_i\}, A_i, B_i)$ say.

Let $k \in I$ be maximum. We may assume that $|I| = m'2^{m''}$. By 5.4 applied to $\mathcal{M}$, there exist

- a subset $I' \subseteq I \setminus \{k\}$ with $|I'| = t = |I|2^{-t}$;
- a subset $C' \subseteq C''$ with $\chi(C') > c'$;
- for each $i \in I'$, a 2-cover $\mathcal{L}_i'$ for $C'$, contained in $\mathcal{L}_i$;
- for each $i \in I'$, an $(\mathcal{L}_i, \mathcal{L}_k)$-diameter $S_i$, such that $V(S_i)$ is anticomplete to $C'$, and $V(S_i) \cap V(\mathcal{L}_i') = \{x_i\}$, and $V(S_i)$ is anticomplete to $V(\mathcal{L}_j')$ for all $j \in I' \setminus \{i\}$.

Let $\mathcal{M}' = (\mathcal{L}_i' : i \in I')$. Then $\mathcal{M}'$ is a 2-multicover of $C'$, and $(S_i : i \in I')$ is a tick on $(\mathcal{M}', C')$ of order at most six, with head $x_k$. This proves 5.5.

This therefore also completes the proof of 4.1. Let us apply it before we go on. By starting with a $k$-multicover $\mathcal{M} = (\mathcal{L}_i : i \in I)$ with $|I|$ large enough, for a set $C$ with chromatic number large enough, and applying 4.1 repeatedly, we obtain a sequence of subsets of $I$, each a subset of its predecessor, and a sequence of multicovers, each contained in its predecessor, and a sequence of ticks all on the last multicover of the sequence $\mathcal{M}'$ say. The ticks are vertex-disjoint except for their vertices in $V(\mathcal{M}')$. There may be edges between them, but if say $(S_i : i \in I)$ and $(T_i : i \in I)$ are two
of these ticks, and some vertex in $S_i$ is adjacent to some vertex in $T_j$, then $i = j$. Consequently we have obtained an impression of $K_{n,n}$ of order at most $k + 4$, with $n$ large, which is impossible if $G$ is $(k + 3, \mu, \nu)$-restricted. We deduce:

5.6 For all $k \geq 2$ and $\mu, \nu, \tau \geq 0$ there exist $m, c \geq 0$ with the following property. Let $G$ be a $(k + 3, \mu, \nu)$-restricted graph such that $\chi^k(G) \leq \tau$. If $C \subseteq V(G)$ with $\chi(C) > c$, then there is no $k$-multicover of $C$ in $G$ with magnitude $m$.

In [4] we proved an analogue of 5.6 for $k = 1$, but it only applies to “independent” 1-multicovers. Let us say a 1-multicover $\mathcal{M} = (\mathcal{L}_i : i \in I)$ is independent if for all $i, j \in I$ with $i < j$, the apex of $\mathcal{L}_j$ has no neighbour in the base of $\mathcal{L}_i$. (Thus, any edge between $V(\mathcal{L}_i)$ and $V(\mathcal{L}_j)$ is between the two bases.) A warning: in [4] we used the term “multicover” to mean what in this paper is called an independent 1-multicover. The result of [4] that we need is the following.

5.7 For all $\mu, \nu, \tau \geq 0$ there exist $m, c \geq 0$ with the following property. Let $G$ be a $(1, \mu, \nu)$-restricted graph, such that $\chi(H) \leq \tau$ for every induced subgraph $H$ of $G$ with $\omega(H) < \nu$. If $C \subseteq V(G)$ with $\chi(C) > c$, then there is no independent 1-multicover of $C$ in $G$ with magnitude $m$.

6 Reducing control

In this section we prove a result of great importance (for us), the following.

6.1 Let $\mu, \nu \geq 0$ and $\rho \geq 2$. Every $\rho$-controlled class of $(\rho + 2, \mu, \nu)$-restricted graphs is 2-controlled.

Proof. The result is trivial for $\rho = 2$, and we proceed by induction on $\rho$. Let $\rho \geq 3$, and let $\mathcal{C}$ be a $\rho$-controlled class of $(\rho + 2, \mu, \nu)$-restricted graphs. Let $\phi$ be nondecreasing such that every graph in $\mathcal{C}$ is $(\rho, \phi)$-controlled. Let $\mathcal{C}^+$ be the class of all induced subgraphs of graphs in $\mathcal{C}$. The graphs in $\mathcal{C}^+$ are also $(\rho, \phi)$-controlled and $(\rho + 2, \mu, \nu)$-restricted.

Let $\tau \geq 0$, and let $\mathcal{D}$ be the set of all graphs $H \in \mathcal{C}^+$ with $\chi^{\rho - 1}(H) \leq \tau$. Let $m, c$ satisfy 5.6, setting $k = \rho - 1$. Then from 5.6 we have:

1. If $G \in \mathcal{D}$, and $C \subseteq V(H)$ with $\chi(C) > c$, then there is no $(\rho - 1)$-multicover of $C$ in $H$ with magnitude $m$.

Define $c_0 = c$, and inductively $c_t = \phi(c_{t-1} + \tau)$ for $t \geq 1$. We claim:

2. For $0 \leq t \leq m$, if $H \in \mathcal{D}$, and $C \subseteq V(H)$ with $\chi(C) > c_t$, then there is no $(\rho - 1)$-multicover of $C$ in $H$ with magnitude $m - t$.

For this is true if $t = 0$, by (1). Let $t \geq 1$ with $t \leq m$, and suppose that the claim holds for $t - 1$. Let $H \in \mathcal{D}$, and $C \subseteq V(H)$ with $\chi(C) > c_t$, and suppose that $\mathcal{M}$ is a $(\rho - 1)$-multicover of $C$ in $H$ with magnitude $m - t$. Let $\mathcal{M} = (\mathcal{L}_i : i \in \{1, \ldots, m - t\})$ say. Let $J = H[C]$. Since $H$ is $(\rho, \phi)$-controlled, $\chi(J) \leq \phi(\chi^\rho(J))$, and therefore

$$\phi(c_{t-1} + \tau) = c_t < \phi(\chi^\rho(J)).$$
Consequently $c_{t-1} + \tau < \chi^\rho(J)$ since $\phi$ is nondecreasing; that is, $c_{t-1} + \tau < \chi(N^\rho_J[v])$ for some vertex $v$ of $J$. Since $\chi(N^\rho_J[v]) \leq \tau$, it follows that $c_{t-1} < \chi(N^\rho_J(v))$. For $0 \leq i \leq \rho$, let $L_i$ be the set of vertices in $V(J)$ with distance $i$ from $v$ in $J$. In particular, $N^\rho_J(v) = L_\rho$, and so $\chi(L_\rho) > c_{t-1}$.

Now $(L_0, \ldots, L_\rho)$ is a levelling in $J$ and hence in $H$; let $L_{m-t+1} = (L_0, \ldots, L_{\rho-1})$. Then $L_{m-t+1}$ is a $(\rho-1)$-cover of $L_\rho$, and so $(L_i : i \in \{1, \ldots, m-t+1\})$ is a $(\rho-1)$-multicover of $L_\rho$ in $H$ with magnitude $m-t+1$. Since $\chi(L_\rho) > c_{t-1}$, this contradicts the inductive hypothesis. Consequently there is no such $M$. This completes the inductive proof of (2).

(3) If $H \in \mathcal{D}$, then $\chi(H) \leq c_m$.

This follows from (2) by setting $t = m$.

(4) For all $\tau \geq 0$, there exists $\phi'(\tau)$ such that $\chi(H) \leq \phi'(\chi^{\rho-1}(H))$ for all $H \in \mathcal{C}^+$.

At the start of the proof we made an arbitrary choice of $\tau$, and all the subsequent variables in (2) and (3) (such as $\mathcal{D}, m$ and the sequence $c_0, c_1, \ldots$) depend on $\tau$. In particular, $c_m$ is a function of $\tau$, say $\phi'(\tau)$. If $H \in \mathcal{C}^+$, then setting $\tau = \chi^{\rho-1}(H)$ in (3) implies that $\chi(H) \leq \phi'(\chi^{\rho-1}(H))$. This proves (4).

We may assume that $\phi'$ is nondecreasing. Then (4) asserts that all graphs in $\mathcal{C}$ are $(\rho-1, \phi')$-controlled, and so $\mathcal{C}$ is $(\rho-1)$-controlled, and hence 2-controlled, from the inductive hypothesis. This proves 6.1.

Let us deduce 1.6, and before that, here is a useful lemma.

**6.2** Let $\rho \geq 2$, and let $\mathcal{C}$ be a class of graphs, such that for all $\nu \geq 0$, the class $\mathcal{C}_\nu$ of graphs $G \in \mathcal{C}$ with $\omega(G) \leq \nu$ is $\rho$-controlled. Then $\mathcal{C}$ is $\rho$-controlled.

**Proof.** For each $\nu \geq 0$, let $\phi_\nu$ be a function such that each graph $G$ in $\mathcal{C}_\nu$ is $(\rho, \phi_\nu)$-controlled. For $c \geq 0$, let $\psi(c) = \max_{\nu \leq c} \phi_\nu(c)$. We claim that $\mathcal{C}$ is $(\rho, \psi)$-controlled. For let $G \in \mathcal{C}$, and let $H$ be an induced subgraph of $G$ such that $\chi(H) > \psi(c)$, for some $c$. Let $\nu = \omega(G)$. If $\nu > c$, then choose a clique $X$ of $H$ with $|X| > c$, and choose $v \in X$; then $X$ belongs to $N^\rho_H[v]$, and so $\chi^\rho(H) \geq |X| > c$ as required. Thus we may assume that $\nu \leq c$, and so $\chi(H) > \phi_\nu(c)$. Since $G$ is $(\rho, \phi_\nu)$-controlled, it follows that $\chi^\rho(H) > c$ as required. This proves 6.2.

Now we prove 1.6, which we restate.

**6.3** Let $\mu \geq 0$ and $\rho \geq 2$, and let $\mathcal{C}$ be a $\rho$-controlled class of graphs. The class of all graphs in $\mathcal{C}$ that do not contain any of $K^{1}_{\mu, \mu}, \ldots, K^{\rho+2}_{\mu, \mu}$ as an induced subgraph is 2-controlled.

**Proof.** Let $\mathcal{D}$ be the class of all graphs in $\mathcal{C}$ that do not contain any of $K^{1}_{\mu, \mu}, \ldots, K^{\rho+2}_{\mu, \mu}$ as an induced subgraph. Let $\nu \geq 0$, and let $\mathcal{D}_\nu$ be the class of all graphs $G \in \mathcal{D}$ with $\omega(G) \leq \nu$. Every graph in $\mathcal{D}_\nu$ is therefore $(\rho + 2, \mu, \nu)$-restricted, and so $\mathcal{D}_\nu$ is 2-controlled by 6.1. From 6.2 it follows that $\mathcal{D}$ is 2-controlled. This proves 6.3.
7 Clique control

Now we come to the second part of the paper, in which we handle 2-controlled graphs. We will follow the approach taken in [4]; and in particular, it will be helpful to introduce a refinement of control, called “clique-control”. If $X$ is a clique with $|X| = \xi$ we call $X$ a $\xi$-clique. We denote by $N^i_H(X)$ the set of all vertices in $V(G) \setminus X$ that are complete to $X$; and by $N^c_H(X)$ the set of all vertices in $V(G) \setminus X$ with a neighbour in $N^1(X)$ and no neighbour in $X$. When $X = \{v\}$ we write $N^i_G(v)$ for $N^i_G(X)$ ($i = 1, 2$). We are assuming that in every induced subgraph $H$ of large $\chi$, there is a vertex $v$ such that $N^2_H(v)$ also has large $\chi$; and perhaps the same is true for cliques larger than singletons. For instance, it may or may not be true that in every induced subgraph $H$ of large $\chi$, there is a 2-clique $X$ such that $N^2_H(X)$ also has large $\chi$. If this is false, we can find induced subgraphs $H$ of arbitrarily large $\chi$ such that $N^2_H(X)$ has bounded $\chi$ for all 2-cliques $X$, and we focus on these subgraphs. If it is true, then we ask the same question for triples, and so on; we must soon hit a clique-size for which the answer is “false”, because none of our graphs have a clique larger than $\nu$.

Let us say this more precisely.

If $\mathcal{C}$ is a class of graphs, we denote by $\mathcal{C}^+$ the class of all induced subgraphs of members of $\mathcal{C}$. Let $\phi : \mathbb{N} \to \mathbb{N}$ be a nondecreasing function, and let $\xi \geq 1$ be an integer. We say a graph $G$ is ($\xi, \phi$)-clique-controlled if for every induced subgraph $H$ of $G$ and every integer $n \geq 0$, if $\chi(H) > \phi(n)$ then there is a $\xi$-clique $X$ of $H$ such that $\chi(N^2(X)) > n$. Roughly, this means that in every induced subgraph $H$ of large chromatic number, there is a $\xi$-clique $X$ with $N^2_H(X)$ of large chromatic number. We say a class of graphs $\mathcal{C}$ is $\xi$-clique-controlled if there is a nondecreasing function $\phi$ such that every graph in $\mathcal{C}$ is ($\xi, \phi$)-clique-controlled. Since we are now concerned with a 2-controlled class of graphs, it is 1-clique-controlled (with some care for the difference between $N^1(v)$ and $N^1[v]$); and since there is an upper bound on the clique number of all these graphs, there is certainly a largest $\xi$ such that the class is $\xi$-clique-controlled, and the next result exploits this. (Note that this works in the opposite direction from control; there we chose $\rho$ minimum such that the class was $\rho$-controlled.)

7.1 Let $\nu \geq 1$ and $\tau_1 \geq 0$, and let $\mathcal{C}$ be a class of graphs such that

- $\mathcal{C}$ is 2-controlled;
- $\omega(G) \leq \nu$ for each $G \in \mathcal{C}$;
- $\chi(H) \leq \tau_1$ for every $H \in \mathcal{C}^+$ with $\omega(H) < \nu$; and
- there are graphs in $\mathcal{C}$ with arbitrarily large chromatic number.

Then there exist $\xi$ with $1 \leq \xi \leq \nu$ and $\tau_2 \geq 0$ with the following properties:

- $\mathcal{C}$ is $\xi$-clique-controlled; and
- for all $c \geq 0$ there is a graph $H \in \mathcal{C}^+$ with $\chi(H) > c$, such that $\chi(N^2_H(X)) \leq \tau_2$ for every $(\xi + 1)$-clique $X$ of $H$.

**Proof.** Suppose that $\mathcal{C}$ is $\nu$-clique-controlled, and choose a function $\phi$ such that every graph in $\mathcal{C}$ is ($\nu, \phi$)-clique-controlled. Let $c = \phi(0)$; then by hypothesis, there exists $G \in \mathcal{C}$ with $\chi(G) > c$. From the definition of ($\nu, \phi$)-clique-controlled, there is a $\nu$-clique $X$ in $G$ with $\chi(N^2(X)) > c$, which is impossible since $N^1(X) = \emptyset$ (because $\omega(G) \leq \nu$).
This proves that $\mathcal{C}$ is not $\nu$-clique-controlled. We claim that $\mathcal{C}$ is 1-clique-controlled. For choose $\phi$ such that every graph in $\mathcal{C}$ is $(2, \phi)$-controlled; and let $\phi'(\epsilon) = \phi(\epsilon + \tau + 1)$ for each $\epsilon \geq 0$. We claim that for every $G \in \mathcal{C}$, with $\chi(H) > \phi'(\epsilon)$. Then $\chi(H) > \phi(c + \tau + 1)$, and since $G$ is $(2, \phi)$-controlled, it follows that $\chi_2(H) > c + \tau_1 + 1$. Hence there is a vertex $v$ of $H$ such that $\chi(N_H^2[v]) > c + \tau_1 + 1$. Now $\chi(N_H^2[v]) \leq \tau_1 + 1$, since the subgraph of $H$ induced on $N_H^2(v)$ has clique number at most $\nu - 1$. Consequently $\chi(N_H^2(v)) > c$. This proves that $\mathcal{C}$ is 1-clique-controlled.

Choose $\xi$ maximum such that $\mathcal{C}$ is $\xi$-clique-controlled; then $1 \leq \xi < \nu$. Suppose that for all $\kappa \geq 0$, there exists $m_\kappa$ such that for every $G \in \mathcal{C}$ and every induced subgraph $H$ of $G$ with $\chi(H) > m_\kappa$, there is a $(\xi + 1)$-clique $X$ of $H$ with $\chi(N_H^2(X)) > \kappa$. Then $G$ is $(\xi + 1, \phi')$-clique-controlled, where we define $\phi'(\kappa) = m_\kappa$ for each $\kappa \geq 0$ (having arranged that $m_0 \leq m_1 \leq \ldots$). Consequently $\mathcal{C}$ is $(\xi + 1)$-clique-controlled, a contradiction.

Thus there exists $\kappa \geq 0$ such that for all $c$, there are graphs $H \in \mathcal{C}^+$ such that $\chi(H) > c$ and $\chi(N_H^2(X)) \leq \kappa$ for every $(\xi + 1)$-clique $X$ of $H$. Let $\tau_2 = \kappa$. This proves 7.1.

We already mentioned independent 1-multicovers earlier; now we need a generalization, using $\xi$-cliques instead of singletons. Let $G$ be a graph, and $X, N, W, C \subseteq V(G)$, such that

- $X, N, C$ are pairwise disjoint, and $X, N, C \subseteq W$;
- $X$ is a $\xi$-clique;
- $X$ is complete to $N$;
- $X$ is anticomplete to $C$; and
- $N$ covers $C$.

We say that the triple $\mathcal{L} = (X, N, W)$ is a $\xi$-clique-cover of $C$. We write $X(\mathcal{L}) = X$, $N(\mathcal{L}) = N$, and $W(\mathcal{L}) = W$. (The purpose of the sets $W$ is not yet evident; they will become important when we talk about skew pairs in the next section, but in this section they are just carried along.)

A $\xi$-clique-multicover of $C$ is a family $(\mathcal{L}_i : i \in I)$ of $\xi$-clique-covers of $C$, where $I$ is a set of integers, such that for all $i, j \in I$ with $i < j$:

- $W(\mathcal{L}_j) \subseteq W(\mathcal{L}_i)$; and
- $X_i$ is anticomplete to $W_j$.

Its magnitude is $|I|$, and its chromatic number is $\chi(C)$.

For $i, j \in I$ with $i < j$, we say that the pair $(\mathcal{L}_i, \mathcal{L}_j)$ is independent (with respect to $C$) if there exists $x_j \in X(\mathcal{L}_j)$ such that no vertex in $N(\mathcal{L}_i)$ with a neighbour in $C$ is adjacent to $x_j$. A $\xi$-clique-multicover $\mathcal{M} = (\mathcal{L}_i : i \in I)$ of $C$ is independent if all its pairs $(\mathcal{L}_i, \mathcal{L}_j)$ (where $j > i$) are independent.

For brevity, let us say a graph $G$ is $(\xi, \zeta, c)$-free if for each $C \subseteq V(G)$ with $\chi(C) > c$, there is no independent $\xi$-multicover of $C$ with magnitude $\zeta$.

We proved in [4], where these objects (with the sets $W$ removed) were called “$\xi$-cables of type 1 and length $|I|$” (the proof is immediate from 5.7 via Ramsey’s theorem), that

7.2 For all $\tau_1, \mu, \nu \geq 0$ and $\xi \geq 1$, there exist $m \geq 1$ and $c \geq 0$ with the following property. Let $G$ be a $(1, \mu, \nu)$-restricted graph, such that $\chi(H) \leq \tau_1$ for every induced subgraph $H$ of $G$ with $\omega(H) < \nu$. Then $G$ is $(\xi, m, c)$-free.
Let $\phi$ be nondecreasing, and let $\xi, \zeta \geq 0$. We say that $G$ is $(\xi, \zeta, \phi)$-multiclique-controlled if for every induced subgraph $H$ of $G$ and all $c \geq 0$, if $\chi(H) > \phi(c)$ then $H$ is not $(\xi, \zeta, c)$-free. We say a class of graphs is $(\xi, \zeta)$-clique-controlled if there is a function $\phi$ such that all graphs in the class are $(\xi, \zeta, \phi)$-multiclique-controlled.

7.3 For all $\tau_1, \mu, \nu \geq 0$ and $\xi \geq 1$, there exists $\zeta_0 \geq 1$ with the following property. Let $\mathcal{C}$ be a class of graphs such that

- $\mathcal{C}$ is $(\xi, \zeta_0)$-multiclique-controlled;
- every graph in $\mathcal{C}$ is $(1, \mu, \nu)$-restricted; and
- $\chi(H) \leq \tau_1$ for all $H \in \mathcal{C}^+$ with $\omega(H) < \nu$.

Then there exists $c$ such that all graphs in $\mathcal{C}$ have chromatic number at most $\phi(c) = c$.

Proof. Let $m, c'$ satisfy 7.2 (with $c$ replaced by $c'$), and let $\zeta_0 = m$; and suppose that $\mathcal{C}$ is a class of graphs that is $(\xi, \zeta_0)$-controlled, and all graphs $G \in \mathcal{C}$ are $(1, \mu, \nu)$-restricted, and $\chi(H) \leq \tau_1$ for all $H \in \mathcal{C}^+$ with $\omega(H) < \nu$. Choose a function $\phi$ such that all graphs in $\mathcal{C}$ are $(\xi, \zeta_0, \phi)$-multiclique-controlled. We claim that $c = \phi(c')$ satisfies the theorem. If there exists $G \in \mathcal{C}$ with $\chi(G) > \phi(c')$, then from the definition of “$(\xi, \zeta_0, \phi)$-multiclique-controlled”, $G$ is not $(\xi, \zeta_0, c')$-free, contrary to 7.2. Consequently every graph in $\mathcal{C}$ has chromatic number at most $\phi(c') = c$. This proves 7.3.

Thus, from 7.3, for all $\tau_1, \mu, \nu \geq 0$ and $\xi \geq 1$, there exists $\zeta_0$ such that for every $\xi$-clique-controlled class $\mathcal{C}$ of $(1, \mu, \nu)$-restricted graphs such that $\chi(H) \leq \tau_1$ for every all $H \in \mathcal{C}^+$ with $\omega(H) < \nu$, if there are graphs in $\mathcal{C}$ with arbitrarily large chromatic number, then there is a maximum $\zeta$ such that $\mathcal{C}$ is $(\xi, \zeta)$-multiclique-controlled, and $\zeta < \zeta_0$. That motivates the following.

7.4 For all $\xi, \zeta \geq 1$, let $\mathcal{C}$ be a class of graphs that is $(\xi, \zeta)$-multiclique-controlled and not $(\xi, \zeta + 1)$-multiclique-controlled. Then there exists $\tau_3$ such that for all $c$, some graph in $\mathcal{C}^+$ has chromatic number more than $c$, and is $(\xi, \zeta + 1, \tau_3)$-free.

Proof. Choose $\phi$ such that every graph in $\mathcal{C}$ is $(\xi, \zeta, \phi)$-multiclique-controlled. If for all $\sigma \geq 0$ there exists $m_\sigma$ such that no $H \in \mathcal{C}^+$ with $\chi(H) > m_\sigma$ is $(\xi, \zeta + 1, \sigma)$-free, then, defining $\phi'(\sigma) = m_\sigma$ (and having arranged that $m_0 \leq m_1 \leq m_2 \leq \ldots$), it follows that every graph in $\mathcal{C}$ is $(\xi, \zeta + 1, \phi')$-multiclique-controlled, and hence $\mathcal{C}$ is $(\xi, \zeta + 1)$-multiclique-controlled, a contradiction. Consequently, for some $\sigma$ there is no such $m_\sigma$; that is, there exists $\tau_3$ as in the theorem. This proves 7.4.

In our search for the graphs in our class that contain trees of chandeliers, we will focus on the induced subgraphs mentioned in 7.4. We will show the following, in later sections. (A “tree of lamps” is defined later, and is closely related to a tree of chandeliers).

7.5 Let $\xi, \zeta \geq 1$, and $\tau_1, \tau_2, \tau_3 \geq 0$. Let $T$ be a tree of lamps. Let $\mathcal{C}$ be a class of graphs such that

- $\chi(H) \leq \tau_1$ for every $H \in \mathcal{C}^+$ with $\omega(H) < \omega(G)$;
- $\mathcal{C}$ is $(\xi, \zeta)$-multiclique-controlled;
• \( \chi(N_2^2(X)) \leq \tau_2 \) for every \( G \in \mathcal{C} \) and every \((\xi + 1)\)-clique \( X \) in \( G \);
• every member of \( \mathcal{C} \) is \((\xi, \zeta + 1, \tau_3)\)-free; and
• no graph in \( \mathcal{C} \) contains \( T \) as an induced subgraph.

Then there exists \( c \) such that every graph in \( \mathcal{C} \) has chromatic number at most \( c \).

Before we begin the proof of 7.5, let us assume its truth and unravel the various inductions implicit in 7.4, 7.3 and 7.1.

7.6 Let \( \xi, \zeta \geq 1 \), and \( \tau_1, \tau_2 \geq 0 \), and let \( T \) be a tree of lamps. Let \( \mathcal{C} \) be a class of graphs such that

• \( \chi(H) \leq \tau_1 \) for every \( H \in \mathcal{C}^+ \) with \( \omega(H) < \omega(G) \);
• \( \chi(N_2^2(X)) \leq \tau_2 \) for every \((\xi + 1)\)-clique \( X \) in \( G \);
• \( \mathcal{C} \) is \((\xi, \zeta)\)-multiclique-controlled; and
• no graph in \( \mathcal{C} \) contains \( T \) as an induced subgraph.

Then \( \mathcal{C} \) is \((\xi, \zeta + 1)\)-multiclique-controlled.

Proof (assuming 7.5): Suppose that \( \mathcal{C} \) is not \((\xi, \zeta + 1)\)-multiclique-controlled, and let \( \tau_3 \) be as in 7.4. Let \( \mathcal{D} \) be the class of all \((\xi, \zeta + 1, \tau_3)\)-free graphs in \( \mathcal{C}^+ \). By 7.4 applied to \( \mathcal{C} \), there are graphs in \( \mathcal{D} \) with arbitrarily large chromatic number. But by 7.5 applied to \( \mathcal{D} \), there exists \( c \) such that every graph in \( \mathcal{D} \) has chromatic number at most \( c \), a contradiction. Thus \( \mathcal{C} \) is \((\xi, \zeta + 1)\)-multiclique-controlled. This proves 7.6.

7.7 Let \( \tau_1, \tau_2, \mu, \nu \geq 0 \) and \( \xi \geq 1 \), and let \( T \) be a tree of lamps. Let \( \mathcal{C} \) be a class of graphs such that

• \( \mathcal{C} \) is \( \xi \)-clique-controlled;
• all graphs in \( \mathcal{C} \) are \((1, \mu, \nu)\)-restricted;
• \( \chi(H) \leq \tau_1 \) for every \( H \in \mathcal{C}^+ \) with \( \omega(H) < \nu \);
• \( \chi(N_2^2(X)) \leq \tau_2 \) for every \((\xi + 1)\)-clique \( X \) in \( G \); and
• no graph in \( \mathcal{C} \) contains \( T \) as an induced subgraph.

Then there exists \( c \) such that all graphs in \( \mathcal{C} \) have chromatic number at most \( c \).

Proof (assuming 7.5): Let \( \zeta_0, c \) be as in 7.3. Now \( \mathcal{C} \) is \((\xi, 1)\)-multiclique-controlled, and so for all \( \zeta \) with \( 1 \leq \zeta < \zeta_0 \), it follows from 7.6 that \( \mathcal{C} \) is \((\xi, \zeta + 1)\)-multiclique-controlled, and hence \((\xi, \zeta_0)\)-multiclique-controlled. By 7.3, all graphs in \( \mathcal{C} \) have chromatic number at most \( c \). This proves 7.7.
7.8 Let \( \tau_1, \mu, \nu \geq 0 \), and let \( T \) be a tree of lamps. Let \( \mathcal{C} \) be a class of graphs such that

- \( \mathcal{C} \) is 2-controlled;
- all graphs in \( \mathcal{C} \) are \((1, \mu, \nu)\)-restricted;
- \( \chi(H) \leq \tau_1 \) for every \( H \in \mathcal{C}^+ \) with \( \omega(H) < \nu \); and
- no graph in \( \mathcal{C} \) contains \( T \) as an induced subgraph.

Then there exists \( c \) such that all graphs in \( \mathcal{C} \) have chromatic number at most \( c \).

**Proof (assuming 7.5):** Suppose that there are graphs in \( \mathcal{C} \) with arbitrarily large chromatic number, and let \( \xi, \tau_2 \) be as in 7.1. Let \( \mathcal{D} \) be the class of all graphs \( H \in \mathcal{C}^+ \) such that \( \chi(N_{H}^{m_{\xi}}(X)) \leq \tau_2 \) for every \((\xi + 1)\)-clique \( X \) of \( H \). Then from 7.1, \( \mathcal{D} \) is \( \xi \)-clique-controlled, and for all \( c \geq 0 \) there is a graph \( H \in \mathcal{D} \) with \( \chi(H) > c \), contrary to 7.7 applied to \( \mathcal{D} \). This proves 7.8.

Finally, we deduce:

7.9 Let \( \mu, \nu \geq 0 \), and let \( T \) be a tree of lamps. Let \( \mathcal{C} \) be a class of graphs such that

- \( \mathcal{C} \) is 2-controlled;
- all graphs in \( \mathcal{C} \) are \((1, \mu, \nu)\)-restricted; and
- no graph in \( \mathcal{C} \) contains \( T \) as an induced subgraph.

Then there exists \( c \) such that all graphs in \( \mathcal{C} \) have chromatic number at most \( c \).

**Proof (assuming 7.5):** We proceed by induction on \( \nu \). We may assume that \( \nu \geq 1 \) and the result holds for \( \nu - 1 \). Let \( \mathcal{D} \) be the class of all graphs \( H \in \mathcal{C}^+ \) with \( \omega(H) < \nu \). Thus all graphs in \( \mathcal{D} \) are \((1, \mu, \nu - 1)\)-restricted, and so by the inductive hypothesis, there exists \( \tau_1 \) such that all graphs in \( \mathcal{D} \) have chromatic number at most \( \tau_1 \). By 7.8, there exists \( c \) such that all graphs in \( \mathcal{C} \) have chromatic number at most \( c \). This proves 7.9.

We see that 1.4 is an immediate consequence of 7.9. Let us prove 1.5, which we restate:

7.10 For all \( \rho \geq 2 \), every forest of chandeliers is pervasive in every \( \rho \)-controlled class.

**Proof (assuming 7.5):** Let \( \mathcal{C} \) be a \( \rho \)-controlled class, let \( T \) be a forest of chandeliers, and let \( \nu, \ell \geq 0 \). We must show that there exists \( c \) such that for every graph \( G \in \mathcal{C} \) with \( \omega(G) \leq \nu \) and \( \chi(G) > c \), there is an induced subgraph of \( G \) isomorphic to a \((\geq \ell)\)-subdivision of \( T \). Let \( T_1 \) be an \( \ell \)-subdivision of \( T \); then \( T_1 \) is also a forest of chandeliers. Choose a tree of lamps \( T' \) such that some subdivision of \( T_1 \) is an induced subgraph of \( T' \) (that this is always possible is discussed after the definition of “tree of lamps”, later), and choose \( \mu \geq 0 \) such that some subdivision of \( T_1 \) is an induced subgraph of \( K_{1,1}^{\mu,\mu} \) (and hence each of \( K_{\mu,\mu}^{2,2}, \ldots, K_{\mu,\mu}^{\rho^2+2} \) contains some \((\geq \ell)\)-subdivision of \( T \) as an induced subgraph). Let \( \mathcal{C} \) be a \( \rho \)-controlled class, and let \( \mathcal{D} \) be the class of graphs in \( \mathcal{C} \) with clique number at most \( \nu \) such that no induced subgraph is an \((\geq \ell)\)-subdivision of \( T \). It follows that every graph in \( \mathcal{D} \) is \((\rho + 2, \mu, \nu)\)-restricted, and hence \( \mathcal{D} \) is 2-controlled by 6.1. By 7.9 applied to \( \mathcal{D} \) and \( T' \), the members of \( \mathcal{D} \) have bounded chromatic number. This proves 7.10.
8 Skew pairs

If \( v \in V(G) \) and \( Z, W \subseteq V(G) \), and \( \beta \geq 0 \) and \( \xi > 0 \), we say that \( v \) is \((\beta, \xi)\)-earthed via \((Z, W)\) if there is a \( \xi \)-clique \( X \subseteq V(G) \) with \( v \in X \), such that \( \chi(M) > \beta \), where \( M \) is the set of all vertices in \( W \setminus X \) that are anticomplete to \( X \) and have a neighbour in \( Z \) that is complete to \( X \).

Let \( M = (L_i : i \in I) \) be a \( \xi \)-clique-multicover of \( C \) in \( G \). The purpose of the sets \( W(L_i) \) is to enable the following definition. For \( i, j \in I \) with \( i < j \), and \( \beta \geq 0 \), let \( Z \) be the set of vertices in \( N(L_i) \) that are anticomplete to \( C \cup \bigcup_{k \in I, k > j} W(L_k) \); we say that the pair \((L_i, L_j)\) is \( \beta \)-skew (with respect to \( M, C \)) if

- every vertex in \( N(L_i) \setminus Z \) is complete to \( X(L_j) \); and
- every vertex in \( N(L_j) \) is \((\beta, \xi)\)-earthed via \((Z, W(L_j))\).

(Note that whether a pair \((L_i, L_j)\) is independent depends on \( C \) but not on the other members of \( M \); but whether the pair is \( \beta \)-skew depends both on \( C \) and on the other members of \( M \).) We say that \( M \) is \( \beta \)-skewed with respect to \( C \) if \((L_i, L_j)\) is \( \beta \)-skew with respect to \( M, C \) for all \( i, j \in I \) with \( i < j \). We stress that, with \( M, C \) as before, if \( i, j \in I \) with \( i < j \), then the pair \((L_i, L_j)\) is itself a \( \xi \)-clique-multicover of \( C \), and might be \( \beta \)-skewed with respect to \( C \) (as a \( \xi \)-clique-multicover of \( C \)) without being \( \beta \)-skew with respect to \( M, C \); so for a pair in a larger multicover, the statements that it is \( \beta \)-skew and \( \beta \)-skewed have different meanings.

Let \((X, N, W)\) be a \( \xi \)-cover of \( C \), and let \( N' \subseteq N \). If every vertex in \( N \setminus N' \) has a neighbour in \( C \), we say that \((X, N', W)\) is a \( C \)-residue of \((X, N, W)\). Let \( M = (L_i : i \in I) \) be a \( \xi \)-clique-multicover of \( C \), and let \( M' = (L_i' : i \in I') \) be a \( \xi \)-clique-multicover of \( C' \). We say that \( M' \) an \((M, C)\)-residue covering \( C' \); if

- \( I' \subseteq I \);
- \( C' \subseteq C \); and
- \( L_i' \) is a \( C \)-residue of \( L_i \) for each \( i \in I' \).

If \( I' = I \), it is said to be spanning. We need:

**8.1** Let \( M = (L_i : i \in I) \) be a \( \xi \)-clique-multicover of \( C \) in \( G \), and let \( M' = (L_i' : i \in I') \) be an \((M, C)\)-residue covering \( C' \subseteq C \). For all \( i, j \in I' \) with \( i, j \), if \((L_i, L_j)\) is independent with respect to \( C \) then \((L_i', L_j')\) is independent with respect to \( C' \); and if \((L_i, L_j)\) is \( \beta \)-skew with respect to \( M, C \) then \((L_i', L_j')\) is \( \beta \)-skew with respect to \( M', C' \).

**Proof.** Let \( i, j \in I' \) with \( i < j \), such that \((L_i, L_j)\) is independent with respect to \( C \). Consequently there exists \( x_j \in X(L_j) \) such that no vertex in \( N(L_i) \) has a neighbour in \( C \) and is adjacent to \( x_j \); and so no vertex in \( N(L_i') \) has a neighbour in \( C' \) and is adjacent to \( x_j \). Thus \((L_i', L_j')\) is independent with respect to \( C' \).

Let \( Z \) be the set of vertices in \( N(L_i) \) that are anticomplete to \( C \cup \bigcup_{k \in I, k > j} W(L_k) \), and let \( Z' \) be the set of vertices in \( N(L'_i) \) that are anticomplete to \( C' \cup \bigcup_{k \in I', k > j} W(L'_k) \). Then \( Z \subseteq Z' \) (note that \( Z \subseteq N(L_i') \) since \( L_i' \) is a \( C \)-residue of \( L_i \), and no vertex in \( Z \) has a neighbour in \( C \)).

Now assume that \((L_i, L_j)\) is \( \beta \)-skew with respect to \( M, C \). Thus \( N(L_j) \setminus Z \) complete to \( X(L_j) \), and so every vertex in \( N(L_j') \setminus Z' \) is complete to \( X(L'_j) \). Also, every vertex in \( N(L_j) \) is \((\beta, \xi)\)-earthed via \((Z, W(L_j))\), and so every vertex in \( N(L_j') \) is \((\beta, \xi)\)-earthed via \((Z', W(L'_j))\). Thus \((L_i', L_j')\) is \( \beta \)-skew with respect to \( M', C' \). This proves 8.1. □
Note also that if \( C'' \subseteq C' \subseteq C \) and \( M, M', M'' \) are \( \xi \)-clique-multicovers of \( C, C', C'' \) respectively, and \( M' \) is an \((M, C)\)-residue, and \( M'' \) is an \((M', C')\)-residue, then \( M'' \) is an \((M, C)\)-residue (we leave the proof to the reader). We call this transitivity of residues. A set \( V \subseteq V(G) \) is \( \beta \)-homogeneous via \((Z, W)\) if either every vertex in \( V \) is \((\beta, \xi)\)-earthed via \((Z, W)\), or none are.

If \( \mathcal{L} = (L_i : i \in I) \) is a \( \xi \)-clique-multicover of \( C \) in \( G \), a pair \((L_i, L_j)\) is \( \beta \)-tidy with respect to \( M, C \) if it is either independent with respect to \( C \) or \( \beta \)-skew with respect to \( M, C \). If every pair in \( M \) is \( \beta \)-tidy, we say that \( M \) is \( \beta \)-tidied (with respect to \( C \)). Again, for a pair in a larger \( \xi \)-clique-multicover, the statements that it is \( \beta \)-tidy and \( \beta \)-tidied have different meanings. Our next goal is to get rid of the untidy pairs. We begin with \( \xi \)-clique-multicovers of magnitude two.

8.2 Let \( \xi > 0 \) and \( \tau_1, \tau_2, \beta \geq 0 \); and let \( G \) be such that \( \chi(H) \leq \tau_1 \) for every \( H \in \mathcal{C}^+ \) with \( \omega(H) < \omega(G) \), and \( \chi(N^2(X)) \leq \tau_2 \) for every \((\xi + 1)\)-clique \( X \) in \( G \). Define \( \gamma = \beta + \tau_2 + \xi \tau_1 + 1 \). Let \( \mathcal{L} = (L_a, L_b) \) be a \( \xi \)-clique-multicover of \( C \) in \( G \), where \( a < b \), \( L_i = (X_i, N_i, W_i) \) for \( i = a, b \), and \( \chi(C) > (\xi + 1) \gamma \). Suppose that \( X_b \cup N_b \) is \( \gamma \)-homogeneous via \((N_a, W_b)\). Then there exist \( C' \subseteq C \) with \( \chi(C') \geq \chi(C)/(\xi + 1) \), and a \( C \)-residue \( L'_a \) of \( L_a \) covering \( C' \), such that \((L'_a, L_b)\) is \( \beta \)-tidied with respect to \( C' \).

**Proof.** For each \( x \in X_b \), let \( X_x \) be the set of vertices in \( N_a \) that are adjacent to \( x \) and have a neighbour in \( C_x \), and let \( C_x \) be the set of vertices in \( C \) with a neighbour in \( N_a \setminus Y_x \). Suppose that there exists \( x \in X_b \) with \( \chi(C_x) \geq \chi(C)/(\xi + 1) \). Let \( L'_a = (X_a, N_a \setminus Y_x, W_a) \); then \((L'_a, L_b)\) is an \((M, C)\)-residue covering \( C_x \), and is independent with respect to \( C_x \), and therefore \((L'_a, L_b)\) is \( \beta \)-tidied with respect to \( C_x \), and the theorem is satisfied.

Thus we may assume that \( \chi(C_x) < \chi(C)/(\xi + 1) \) for each \( x \in X \). Let \( C' \) be the set of all vertices in \( C \) that are not in any of the sets \( C_x \) \((x \in X_b)\). It follows that \( \chi(C') \geq \chi(C) - \chi(C)_x/(\xi + 1) = \chi(C)/(\xi + 1) \). Let \( U \) be the set of vertices in \( N_a \) that are complete to \( X_b \). Thus every vertex in \( C' \) has no neighbour in any of the sets \( Y_x \) \((x \in X_b)\), and therefore all its neighbours in \( N_a \) belong to \( U \).

We claim that \( M \) itself, with \( C' \), satisfy the theorem in this case. To show this we must show that \((L_a, L_b)\) is \( \beta \)-skew with respect to \( M, C' \). Since \( \chi(C') \geq \chi(C)/(\xi + 1) > \gamma \), and every vertex in \( C' \) has a neighbour in \( U \), and this neighbour is therefore complete to the \( \xi \)-clique \( X_b \), it follows that every vertex in \( X_b \) is \( \gamma \)-earthed via \((N_a, C')\), and therefore via \((N_a, W_b)\). Since \( X_b \cup N_b \) is \( \gamma \)-homogeneous via \((N_a, W_b)\), it follows that every vertex in \( N_b \) is also \( \gamma \)-earthed via \((N_a, W_b)\).

Let \( v \in N_b \). From the definition of “\( \beta \)-earthed”, there is a \( \xi \)-clique \( X \subseteq V(G) \) with \( v \in X \), such that \( \chi(M) > \gamma \), where \( M \) is the set of all vertices in \( W_b \setminus X \) that are anticomplete to \( X \) and have a neighbour in \( N_a \) that is complete to \( X \). Let \( M' \subseteq M \) be the set of vertices in \( M \setminus X_b \) with a neighbour in \( U \) and with no neighbour in \( X_b \); then since \( v \) is complete to \( X_b \), and so by hypothesis \( \chi(N^2(X_b \cup \{v\})) \leq \tau_2 \), it follows that \( \chi(M') \leq \tau_2 \). Also the set \( M'' \) of vertices in \( M \) that either belong to \( X_b \) or have a neighbour in \( X_b \) has chromatic number at most \( \xi \tau_1 + 1 \). Hence

\[
\chi(M \setminus (M' \cup M'')) > \gamma - \tau_2 - \xi \tau_1 - 1 = \beta,
\]

and consequently \( v \) is \( \beta \)-earthed via \((N_a \setminus U, W_b)\). Since no vertex in \( N_a \setminus U \) has a neighbour in \( C' \), it follows that \((L_a, L_b)\) is \( \beta \)-skew with respect to \( M, C' \). This proves 8.2.

From 8.2 we deduce the following (we remark that it was in order to prove this result and its consequence 8.5 that we introduced the concept of being \((\xi, \zeta)\)-multiclique-controlled).
8.3 Let \( \xi > 0 \) and \( \tau_1, \tau_2, \tau_3, \beta \geq 0 \), and \( \phi \) a nondecreasing function. For all \( c' \geq 0 \) there exists \( c \geq 0 \) with the following property. Let \( G \) be such that

- \( \chi(H) \leq \tau_1 \) for every \( H \in C^+ \) with \( \omega(H) < \omega(G) \);
- \( \chi(N^2(X)) \leq \tau_2 \) for every \((\xi + 1)\)-clique \( X \) in \( G \);
- \( G \) is \( (\xi, \zeta, \phi) \)-multiclique-controlled; and
- \( G \) is \( (\xi, \zeta + 1, \tau_3) \)-free.

Let \( L_1 = (X_1, N_1, W_1) \) be a \( \xi \)-clique-cover of \( C \), where \( \chi(C) > c \). Then there exist \( X_2, N_2, W_2 \subseteq C \) and \( C' \subseteq W_2 \) such that \( L_2 = (X_2, N_2, W_2) \) is a \( \xi \)-clique-cover of \( C' \), and \( \chi(C') > c' \), and there is a \( C \)-residue \( L'_1 \) of \( L_1 \) such that \( (L'_1, L_2) \) is \( \beta \)-skewed with respect to \( C' \).

**Proof.** Let \( \gamma = \beta + \tau_2 + \xi \tau_1 + 1 \); and let \( c = 2\phi((\xi + 1)(\xi + 1)^c \max(c', \tau_3)) \). We claim that \( c \) satisfies the theorem. For let \( G, L_1 = (X_1, N_1) \) and \( C \) be as in the theorem, with \( \chi(C) > c \). Let \( D_1 \) be the set of vertices in \( C \) that are \( \gamma \)-earthed via \((N_1, C)\), and \( D_2 = C \setminus D_1 \). Since \( \chi(C) > c \phi((\xi + 1)^c \xi) \), one of \( D_1, D_2 \), say \( D \), has chromatic number larger than \( \phi((\xi + 1)^c \xi) \). Since \( G \) is \( (\xi, \zeta, \phi) \)-multiclique-controlled, it follows that there is an independent \( \xi \)-clique-cover \((L_i : 2 \leq i \leq \xi + 1)\) of some \( C_1 \subseteq D \), with \( \chi(C_1) > (\xi + 1)^c \max(c', \tau_3) \) and \( W(L_i) \subseteq D \) for \( 2 \leq i \leq \xi + 1 \). Now \( D \) is \( \gamma \)-homogeneous via \((N_1, C)\). Let \( 2 \leq i \leq \xi + 1 \), and and let \( L'_i = (X(L_i), N(L_i), D) \). Then \( X(L'_i) \cup N(L_i) \) is \( \gamma \)-homogeneous via \((N_1, C)\). Let \( C_1 = D \). By \( \zeta \) applications of 8.2, to the pairs \((L_1, L'_i)\) for \( i = 2, \ldots, \xi + 1 \) in turn, and successive subsets of \( C_1 \), we deduce that for \( i = 2, \ldots, \xi + 1 \) there exists \( C_i \subseteq C_{i-1} \) with \( \chi(C_i) > \chi(C_i)/(\xi + 1) \), and a \( C_{i-1} \)-residue \( L_{1,i} \) of \( L_1 \), such that the pairs \((L_{1,i}, L'_i)\) are each \( \beta \)-tidied with respect to \( C_i \). In particular, this is true when \( i = \xi + 1 \); let \( C' = C_{\xi + 1} \) and \( L'_1 = L_{1,\xi+1} \). Thus \( \chi(C') > \max(c', \tau_3) \), and \( L'_1 \) is a \( C \)-residue of \( L_1 \). Suppose that each of the pairs \((L'_1, L'_i)\) is independent with respect to \( C' \), for \( i = 2, \ldots, \xi + 1 \); then also the pairs \((L'_1, L_i)\) are independent with respect to \( C \) for \( i = 2, \ldots, \xi + 1 \), and so \((L'_1, L_2, \ldots, L_{\xi+1})\) is an independent \( \xi \)-clique-multicover of \( C' \), which is impossible since \( \chi(C') > \tau_3 \). Thus there exists \( i \in \{2, \ldots, \xi + 1\} \) such that \((L'_1, L'_i)\) is \( \beta \)-skewed with respect to \( C' \). This proves 8.3.

This implies:

8.4 Let \( \xi, t > 0 \) and \( \tau_1, \tau_2, \tau_3, \beta \geq 0 \), and \( \phi \) a nondecreasing function. For all \( c' \geq 0 \) there exists \( c \geq 0 \) with the following property. Let \( G \) be such that

- \( \chi(H) \leq \tau_1 \) for every \( H \in C^+ \) with \( \omega(H) < \omega(G) \);
- \( \chi(N^2(X)) \leq \tau_2 \) for every \((\xi + 1)\)-clique \( X \) in \( G \);
- \( G \) is \( (\xi, \zeta, \phi) \)-multiclique-controlled; and
- \( G \) is \( (\xi, \zeta + 1, \tau_3) \)-free.

Let \( L_1 \) be a \( \xi \)-clique-cover of \( C \), where \( \chi(C) > c \). Then there exist \( C' \subseteq C \) with \( \chi(C') > c' \), and a \( C \)-residue \( L'_1 \) of \( L_1 \) covering \( C' \), and \( \xi \)-clique-covers \( L_2, \ldots, L_t \) of \( C' \), such that

- \( M = (L'_1, L_2, \ldots, L_t) \) is a \( \xi \)-clique-multicovering of \( C' \);
• $\mathcal{M}$ is $\beta$-tidied with respect to $C'$; and

• for $2 \leq i \leq t$, the pair $(\mathcal{L}'_i, \mathcal{L}_i)$ is $\beta$-skew with respect to $\mathcal{M}, C'$.

**Proof.** The result is true when $t = 1$, taking $c' = c$; so we assume that $t > 1$ and the result holds for $t - 1$. Define $\gamma = \beta + \tau_2 + \xi \tau_1 + 1$. Choose $n_2$ such that setting $c = n_2$ satisfies 8.3 when $c'$ is replaced by $(\xi + 1)^{t-2} \max(\gamma, c')$. Choose a value of $c$ that satisfies the result with $t, c'$ replaced by $t - 1, 2^{t-2} n_2$ respectively. We claim that $c$ satisfies the theorem. For let $G, \mathcal{L}_1 = (X_1, N_1, W_1)$ and $C$ be as in the theorem, with $\chi(C) > c$. From the choice of $c$, there exist $D_1 \subseteq C$ with $\chi(D_1) > 2^{\gamma+1} n_2$, and a $C$-residue $\mathcal{L}'_1$ of $\mathcal{L}_1$ covering $D_1$, and $\xi$-clique-covers $\mathcal{L}_2, \ldots, \mathcal{L}_{t-1}$ of $D_1$, such that

• $\mathcal{M}_1 = (\mathcal{L}'_1, \mathcal{L}_2, \ldots, \mathcal{L}_{t-1})$ is a $\xi$-clique-multicovering of $D_1$;

• $\mathcal{M}_1$ is $\beta$-tidied with respect to $D_1$; and

• for $2 \leq i \leq t - 1$, the pair $(\mathcal{L}'_i, \mathcal{L}_i)$ is $\beta$-skew with respect to $\mathcal{M}_1, D_1$.

For $2 \leq i \leq t - 1$, let $\mathcal{L}_i = (X_i, N_i, W_i)$. For each such $i$, there is a partition of $D_1$ into two parts, both $\beta$-homogeneous via $(N_i, D_1)$; and so there is a partition of $D_1$ into $2^{\gamma-t}$ parts, each $\beta$-homogeneous via each of $N_2, \ldots, N_{t-1}$. Let $D_2$ be one of the parts, chosen such that $\chi(D_2) \geq 2^{\gamma-t} \chi(D_1) > n_2$. Now $\mathcal{L}_1$ is a $\xi$-cover of $D_2$, so by 8.3 and the choice of $n_2$, there is a $D_2$-residue $\mathcal{L}_2''$ of $\mathcal{L}'_1$, and $D_3 \subseteq D_2$ with $\chi(D_3) > (\xi + 1)^{t-2} \max(\gamma, c')$, and a $\xi$-clique-cover $\mathcal{L}_i = (X_i, N_i, W_i)$ of $D_3$, such that $W_i \subseteq D_2$, and the pair $(\mathcal{L}'_1, \mathcal{L}_i)$ is $\beta$-skewed with respect to $D_3$. Thus

$$\mathcal{M}_3 = (\mathcal{L}'_1, \mathcal{L}_2, \mathcal{L}_3, \ldots, \mathcal{L}_{t-1}, \mathcal{L}_t)$$

is a $\xi$-clique-multicover of $D_3$. Moreover, $\mathcal{L}_i''$ is a $C$-residue of $\mathcal{L}_1$, by the transitivity of residues.

(1) Every pair of $\mathcal{M}_3$ is $\beta$-tidy with respect to $\mathcal{M}_3, D_3$ except possibly the pairs $(\mathcal{L}_i, \mathcal{L}_i)$ where $2 \leq i \leq t - 1$.

To see this, there are three kinds of pairs to consider:

• The pair $(\mathcal{L}_i'', \mathcal{L}_i)$ where $2 \leq i \leq t - 1$: this pair is $\beta$-tidy with respect to $\mathcal{M}_1, D_1$, and since $W(\mathcal{L}_i) \subseteq D_1$, it is also $\beta$-tidy with respect to $\mathcal{M}_3, D_3$.

• The pair $(\mathcal{L}_i'', \mathcal{L}_i)$: this is chosen to be $\beta$-skewed with respect to $D_3$, and therefore $\beta$-tidy with respect to $\mathcal{M}_3, D_3$.

• The pair $(\mathcal{L}_i, \mathcal{L}_j)$ where $2 \leq i < j \leq t - 1$: again, this is $\beta$-tidy with respect to $\mathcal{M}_1, D_1$, and hence also with respect to $\mathcal{M}_3, D_3$ since $W(\mathcal{L}_i) \subseteq D_1$.

This proves (1).

Let $C_1 = D_3$. By $t - 2$ applications of 8.2, applied to the pairs $(\mathcal{L}_i, \mathcal{L}_i)$ and $C_{i-1}$ for $2 \leq i \leq t - 1$ in turn, we deduce that for $2 \leq i \leq t - 1$ there exist $C_i \subseteq C_{i-1}$ with $\chi(C_i) \geq \chi(C_{i-1})/(\xi + 1)$, and a $C_{i-1}$-residue $\mathcal{L}_i'$ of $\mathcal{L}_i$ covering $C_i$, such that $(\mathcal{L}_i', \mathcal{L}_i)$ is $\beta$-tidied with respect to $C_i$. It follows from 8.1 and (1) that

$$\mathcal{M} = (\mathcal{L}_1'', \mathcal{L}_2', \mathcal{L}_3', \ldots, \mathcal{L}_{t-1}', \mathcal{L}_t')$$  

(setting $C' = C_{t-1}$) satisfies the theorem. This proves 8.4.
By choosing $t$ large enough in 8.4, and applying Ramsey’s theorem to the sequence $(L_2, \ldots, L_t)$, we deduce since $G$ is $(\xi, \zeta + 1, \tau_3)$-free that the same result as 8.4 is true with ”$\beta$-tidied” replaced by “$\beta$-skewed”. This result is important enough that it deserves to be said explicitly:

8.5 Let $\xi, t > 0$ and $\tau_1, \tau_2, \tau_3, \beta \geq 0$, and $\phi$ a nondecreasing function. For all $c' \geq 0$ there exists $c \geq 0$ with the following property. Let $G$ be such that

- $\chi(H) \leq \tau_1$ for every $H \in \mathcal{C}^+$ with $\omega(H) < \omega(G)$;
- $\chi(N^2(X)) \leq \tau_2$ for every $(\xi + 1)$-clique $X$ in $G$;
- $G$ is $(\xi, \zeta, \phi)$-multiclique-controlled; and
- $G$ is $(\xi, \zeta + 1, \tau_3)$-free.

Let $L_1 = (X_1, N_1)$ be a $\xi$-clique-cover of $C$, where $\chi(C) > c$. Then there exist $C' \subseteq C$ with $\chi(C') > c'$, and a $C$-residue $L'_1$ of $L_1$ covering $C'$, and $\xi$-clique-covers $L_2, \ldots, L_t$ of $C'$, such that

- $M = (L'_1, L_2, \ldots, L_t)$ is a $\xi$-clique-multicovering of $C'$;
- $M$ is $\beta$-skewed with respect to $C'$.

9 Finding a tree of lamps

Now we come to reap the benefit of all the complications of 8.5; we show that any graph satisfying the conditions of 8.5 contains any given tree of lamps as an induced subgraph, if the number $t$ and the chromatic number are large enough.

Here at last is a definition of a tree of lamps. Start with a tree $T$ with a vertex called its root; and take a map $w$ from $V(T)$ into the set of positive integers, such that

- every vertex $v$ different from the root has a unique neighbour $u$ with $w(u) > w(v)$ (and consequently the $w$-value of the root is strictly larger than all the other values)
- there is a vertex $v$ with $w(v) = 1$ (necessarily, either $v$ is the root and $|V(T)| = 1$, or $v$ is a leaf of $T$);
- for every vertices $u, v$ with $u \neq v$, if $w(u) = w(v)$ then $w(u) = 1$.

We call such a function $w$ a height function for $T$. Let $w(V(T))$ denote the set $\{w(v) : v \in V(T)\}$.

Now choose a set $J$ of integers, each at least 1 and at most the $w$-value of the root, with $J \cap w(V(T)) = \{1\}$. For each $j \in J$, take a new vertex $x_j$; and make $x_j$ adjacent to $v$ for every edge $uv$ of $T$ such that $w(v) \leq j$ and $w(u) > j$. (If $|V(T)| = 1$, make $x_1$ adjacent to the root.) A graph constructed this way is called a lamp, and $x_1$ is its plug. Thus every chandelier is a lamp, but many lamps are not chandeliers.

Analogously to trees of chandeliers, we can make trees of lamps, by taking a new lamp, and attaching trees of lamps already constructed to this new lamp by their plugs. However, we are not permitted to attach anything to neighbours of the plug. Let us say this more precisely. A spotlight is a one-vertex graph, with plug its vertex. No tree of lamps has negative height; and the spotlight is the only tree of lamps of height zero. Inductively for $r > 0$, having defined trees of lamps of height
≤ r − 1 and their plugs, we proceed as follows. Let L be a lamp with plug ℓ. For each v ∈ V(L), let Q_v be a tree of lamps of height at most r − 1, such that all the graphs L and Q_v(v ∈ V(L)) are pairwise anticomplete, and such that if v is equal to or adjacent to ℓ, then Q_v is a spotlight. Now identify v with the plug of Q_v, for each v ∈ V(L). (More precisely, add new edges joining v to every neighbour of the plug of Q_v, and then delete the plug of Q_v, for each v ∈ V.) Let the result be Q. Any such graph Q, with plug ℓ, is said to be a tree of lamps of height ≤ r (and so is the spotlight).

We say G is a forest of lamps if every component is a tree of lamps.

We used earlier the fact that for every tree of chandeliers H, there is a tree of lamps J such that some subdivision of H is an induced subgraph of J. We leave it to the reader to verify this.

We will show the following.

9.1 Let ξ, ζ > 0 and τ_1, τ_2, τ_3 ≥ 0, and φ a nondecreasing function. Let Q be a tree of lamps. Then there exists c ≥ 0 with the following property. Let G be such that

- \( \chi(H) \leq \tau_1 \) for every \( H \in C^+ \) with \( \omega(H) < \omega(G) \);
- \( \chi(N^2(X)) \leq \tau_2 \) for every \( (\xi+1) \)-clique \( X \) in G;
- G is \( (\xi, \zeta, \phi) \)-multiclique-controlled; and
- G is \( (\xi, \zeta + 1, \tau_3) \)-free.

Let \( L_1 = (X_1, N_1) \) be a \( \xi \)-clique-cover of C, where \( \chi(C) > c \), and let \( a_1 \in X_1 \). Then there is an isomorphism from Q to an induced subgraph of G, mapping the plug of Q to \( a_1 \).

**Proof.** We proceed by induction on \( |V(Q)| \). Certainly it is true if \( |V(Q)| = 1 \), so we assume that \( |V(Q)| > 1 \) and the result holds for all smaller trees of lamps. Since, up to isomorphism, there are only finitely many smaller trees of lamps, we can choose \( c_0 \geq 0 \) such that the theorem is true with \( c \) replaced by \( c_0 \) for every tree of lamps with at most \( |V(Q)| - 1 \) vertices. Let \( \beta = c_0 + |V(Q)|(\tau_2 + (\xi + 1)\tau_1) \).

There is a lamp L with plug ℓ say, and trees of lamps \( Q_v \ (v \in V(L)) \) such that Q is obtained from L and the graphs \( Q_v(v \in V(L)) \) as in the definition above.

There is a tree T, a height function w, a set J of integers, and vertices \( x_j \ (j \in J) \) in L, as in the definition of a lamp. Choose w such that w(v) is congruent to 1 modulo 3 for all v, and every member of J is also congruent to 1 modulo 3. Let \( q_0 \) be the root of T.

Let \( t = w(q_0) \). Choose c such that 8.5 holds with \( c' = 0 \). We claim that c satisfies the theorem.

For let \( G, L_1 = (X_1, N_1) \) and C be as in the theorem. By 8.5, there exist \( C' \subseteq C \) with \( \chi(C') > c' \), and a \( C \)-residue \( L_1' \) of \( L_1 \) covering \( C' \), and \( \xi \)-clique-covers \( L_2, \ldots, L_t \) of \( C' \), such that

- \( M = (L_1', L_2, \ldots, L_t) \) is a \( \xi \)-clique-multicovering of \( C' \); and
- \( M \) is \( \beta \)-skewed with respect to \( C' \).

For \( 1 \leq i \leq t \), let \( L_i = (X_i, N_i, W_i) \); and for \( 1 \leq i < j \leq t \), let \( Z_{i,j} \) be the set of vertices in \( N_i \) that have a neighbour in \( W_j \) and are anticomplete to \( C' \cup W_{j+1} \cup \cdots \cup W_t \). Thus the sets \( Z_{i,i+1}, \ldots, Z_{i,t} \) are pairwise disjoint subsets of \( N_i \), and no vertex of any of them has a neighbour in \( C' \); let \( Y_i = N_i \setminus (Z_{i,i+1} \cup \cdots \cup Z_{i,t}) \). From the definition of “skew”, it follows that
(1) \( Z_{i,k} \) is complete to \( X_j \) for \( 1 \leq i < j < k \leq t \), and \( Y_i \) is complete to \( X_j \) for \( 1 \leq i < j \leq t \).

Also, every vertex in \( N_j \) is \((\beta, \xi)\)-earthed via \((Z_{i,j}, W_j)\).

(2) Let \( 1 \leq i < j \leq t \), and let \( v \in X_h \cup N_h \) for some \( h \in \{1, \ldots, t\} \). Let \( M \) be the set of vertices in \( W_j \) that are equal or adjacent to \( v \), or have a neighbour in \( Z_{i,j} \) adjacent to \( v \). Then \( \chi(M) \leq \tau_2 + (\xi + 1)\tau_1 \), unless either

- \( h < i \) and \( v \in Z_{h,i} \), or
- \( h = i \) and \( v \in X_i \), or
- \( i < h < j \) and \( v \in X_h \), or
- \( h = j \).

There are several cases, depending on the value of \( h \) relative to \( i, j \). We may assume that \( v \) has a neighbour in \( Z_{i,j} \), and so \( h \leq j \); and we may therefore assume that \( h < j \).

Suppose first that some \( \xi \)-clique \( X \) is complete to both \( \{v\} \) and \( Z_{i,j} \). Since \( N^2(X \cup \{v\}) \leq \tau_2 \) (because \( X \cup \{v\} \) is a \((\xi + 1)\)-clique), and \( X \) is complete to \( Z_{i,j} \), it follows that the set of vertices in \( M \) that are adjacent to a neighbour of \( v \) in \( Z_{i,j} \) and anticomplete to \( X \cup \{v\} \) has chromatic number at most \( \tau_2 \). But the chromatic number of the set of vertices in \( M \) that belong to or have a neighbour in \( X \cup \{v\} \) is at most \( (\xi + 1)\tau_1 \); and so \( \chi(M) \leq \tau_2 + (\xi + 1)\tau_1 \), and the result holds. Thus we may assume that there is no such \( X \). In particular, \( v \) is not complete to \( X_i \). Also, since we may assume that \( v \notin X_i \), it follows that \( h \neq i \); and so either \( i < h < j \), or \( h < i \).

If \( i < h < j \), we may assume that \( v \notin X_h \), and so \( v \notin N_h \); but then the \( \xi \)-clique \( X_h \) is complete to \( \{v\} \) and to \( Z_{i,j} \) by (1), a contradiction.

Thus \( h < i \). Then since \( v \) has a neighbour in \( Z_{i,j} \), it follows that \( v \notin N_h \); and so by (1), \( v \in Z_{h,k} \) for some \( k \leq i \). Since \( v \) has a neighbour in \( N_i \), it follows that \( k = i \), as required. This proves (2).

Now we begin to construct the isomorphism \( \eta \) from \( Q \) to an induced subgraph of \( G \). We recall that \( \tau_0 \) is the root of \( T \); choose some vertex in \( N_1 \), and call it \( \eta(q_0) \). At a general stage of the process, we will have defined \( \eta(p) \) only for the vertices \( p \) in a subset \( \text{dom}(\eta) \) of \( V(Q) \). We will ensure that \( \eta \) is injective, and for all \( u, v \in \text{dom}(\eta) \), \( u, v \) are adjacent in \( Q \) if and only if \( \eta(u), \eta(v) \) are adjacent in \( G \).

First we extend \( \text{dom}(\eta) \) to equal \( V(T) \), in such a way that \( \eta(p) \in N_{w(p)} \) for each \( p \in V(T) \), by repeating the following process.

- Choose an integer \( n \) maximum such that \( w(v) = n \) for some \( v \in V(T) \notin \text{dom}(\eta) \). (When this is not possible stop.)
- Let \( u \) be the neighbour of \( v \) in \( \text{dom}(\eta) \) (necessarily unique).
- Choose a vertex \( y \in Z_{w(u), w(v)} \) adjacent to \( \eta(u) \) and nonadjacent to all the vertices \( \eta(p)(p \in \text{dom}(\eta) \setminus \{u\}) \). To see that this is possible, let \( p \in \text{dom}(\eta) \setminus \{u\} \). Since \( w(p) > n \), and \( \eta(p) \) belongs to \( N_{w(p)} \), and therefore \( w(p) \neq w(u) \), it follows from (2) that the set of vertices in \( W_{w(u)} \) that have a neighbour in \( Z_{w(v), w(u)} \) adjacent to \( \eta(p) \) has chromatic number at most \( \tau_2 + (\xi + 1)\tau_1 \). Consequently the set of vertices in \( W_{w(u)} \) that have a neighbour in \( Z_{w(v), w(u)} \) with a neighbour...
in \(\{\eta(p) : p \in \text{dom}(\eta) \setminus \{u\}\}\) has chromatic number at most \(|V(Q)|(\tau_2 + (\xi + 1)\tau_1)\). Since \(\eta(u)\) is \((\beta, \xi)\)-earthed via \((Z_{W(v),w(u)}, W_{w(u)})\), and \(\beta > |V(Q)|(\tau_2 + (\xi + 1)\tau_1)\), there is at least one vertex \(x \in W_{w(u)}\) that has a neighbour in \(y \in Z_{W(v),w(u)}\) adjacent to \(w(u)\), and has no neighbour in \(Z_{w(v),w(u)}\) that is adjacent to any of \(\eta(p)(p \in \text{dom}(\eta) \setminus \{u\})\). In particular, \(y\) is nonadjacent to all of \(\eta(p)(p \in \text{dom}(\eta) \setminus \{u\})\). This shows the existence of the vertex \(y\) as claimed.

- Define \(\eta(v) = y\), and add \(v\) to \(\text{dom}(\eta)\).

Next we add all the vertices \(x_j(j \in J)\) to \(\text{dom}(\eta)\), defining \(\eta(x_j)\) to be some vertex in \(X_j\) for each \(j \in J\), and in particular choosing \(\eta(x_1) = a_1\). By \((1)\), \(\eta\) still defines an isomorphism from \(\text{dom}(\eta)\) into \(V(G)\).

Now we turn to adding the “pendant” trees of lamps \(Q_v(v \in V(L))\). We proceed as follows.

- For \(n = t, t - 3, t - 6, \ldots, 1\) in turn, do the following.
- If \(n = 1\), then since all the \(Q_v\) are spotlights when \(w(v) = 1\), the process stops. So we assume that \(n \geq 2\).
- If \(n \notin J\) and there is no \(p \in V(T)\) with \(w(p) = n\), continue to the next value of \(n\).
- Suppose that there exists \(u \in V(T)\) with \(w(u) = n\). Then \(u\) is unique (since \(n \geq 1\)), and \(n \notin J\).
  - Now \(\eta(u)\) is \((\beta, \xi)\)-earthed via \((Z_{n-1,n}, W_n)\). For each \(p \in \text{dom}(\eta)\), either \(p \in V(T)\), or \(p = x_j\) for some \(j \in J\), or \(p\) is a vertex of some \(Q_v\) where \(w(v) > n\). In each case, let \(f(p)\) be the chromatic number of the set of vertices in \(W_n\) that are either equal or adjacent to \(\eta(p)\), or are adjacent to a neighbour of \(\eta(p)\) in \(Z_{n-1,n}\). We need to bound \(f(p)\) in each case. In the first case, when \(p \in V(T)\), it follows that \(w(p)\) is congruent to 1 modulo 3, and so \(w(p) \neq n - 1\); and also \(\text{dom}(\eta) \cap Z_{h,n-1} = \emptyset\) for \(h < n - 1\), since \(n - 1\) is divisible by 3 and therefore we have so far used no vertices from it. So by \((2)\), \(f(p) \leq \tau_2 + (\xi + 1)\tau_1\). In the second case, when \(p = x_j\) for some \(j \in J\), it follows that \(j\) is 1 modulo 3, and so \(j \neq n - 1\) and again \((2)\) implies that \(f(p) \leq \tau_2 + (\xi + 1)\tau_1\). In the third case, when \(p\) is a vertex of some \(Q_v\), then \(\eta(p) \in W_{w(v)}\), and therefore is anticomplete to \(Z_{n-1,n}\); and so \(f(p) \leq \tau_1\). In total then, the set of vertices in \(W_n\) that either belong to or have a neighbour in \(\{\eta(p) : p \in \text{dom}(\eta)\}\), or have a neighbour in \(Z_{n-1,n}\) which has a neighbour in this set, has chromatic number at most \(|V(Q)|(\tau_2 + (\xi + 1)\tau_1) = \beta - c_0\). Consequently there exist \(Z \subseteq Z_{n-1,n}\) and \(W \subseteq W_n\), such that \(Z \cup W\) is anticomplete to \(\{\eta(p) : p \in \text{dom}(\eta)\}\), and such that \(\eta(u)\) is \((c_0, \xi)\)-earthed via \((Z, W)\). From the inductive hypothesis, there is an automorphism from \(Q_u\) to an induced subgraph of \(G[Z \cup W \cup \{\eta(u)\}]\), mapping the plug of \(Q_u\) to \(\eta(u)\). This provides the desired extension of \(\eta\) and \(\text{dom}(\eta)\) to include \(V(Q_u)\). Then go to the next value of \(n\).
- Finally, suppose that \(n \in J\). Then \(n < t\), and so there are vertices in \(N_{n+1}\). Now every vertex in \(N_{n+1}\) is \((\beta, \xi)\)-earthed via \((Z_{n-1,n+1}, W_{n+1})\), and since \(\eta(x_n)\) is anticomplete to \(W_{n+1}\) and complete to \(Z_{n-1,n+1}\) by \((1)\), it follows that \(\eta(x_n)\) is also \((\beta, \xi)\)-earthed via \((Z_{n-1,n+1}, W_{n+1})\).

This completes the construction of the isomorphism, and so completes the proof of 9.1.
We deduce 7.5, which we restate:

**9.2** Let $\xi, \zeta \geq 1$, and $\tau_1, \tau_2, \tau_3 \geq 0$. Let $T$ be a tree of chandeliers. Let $\mathcal{C}$ be a class of graphs such that

- $\chi(H) \leq \tau_1$ for every $H \in \mathcal{C}^+$ with $\omega(H) < \omega(G)$;
- $\mathcal{C}$ is $(\xi, \zeta)$-multiclique-controlled;
- $\chi(N_2^G(X)) \leq \tau_2$ for every $G \in \mathcal{C}$ and every $(\xi + 1)$-clique $X$ in $G$;
- every member of $\mathcal{C}$ is $(\xi, \zeta + 1, \tau_3)$-free; and
- no graph in $\mathcal{C}$ contains $T$ as an induced subgraph.

Then there exists $c$ such that every graph in $\mathcal{C}$ has chromatic number at most $c$.

**Proof.** Choose $\phi$ such that every graph in $\mathcal{C}$ is $(\xi, \zeta, \phi)$-multiclique-controlled. Choose $c'$ such that 9.1 is satisfied with $c, Q$ replaced by $c', T$, and let $c = \phi(c')$. We claim that $c$ satisfies the theorem. For let $G$ be as in the theorem, and suppose that $\chi(G) > c$. Since $\chi(G) > \phi(c')$, there is a $\xi$-clique $X_1$ of $G$ with $\chi(N^2(X_1)) > c'$. By 9.1, $G$ contains $T$ as an induced subgraph, a contradiction. This proves that $\chi(G) \leq c$, and so proves 7.5.

## 10 Out of control

What about general graphs, what can we say about the pervasive graphs for the class of all graphs? Any such graph must be a forest of chandeliers, and perhaps the converse is true, but we have no proof. We do have the following.

**10.1** Let $H$ be a tree of chandeliers. Suppose that for all $\ell \geq 1$ and $\nu, \tau_1 \geq 0$ there exists $\rho \geq 2$, such that for all $\tau_2 \geq 0$, every graph $G$ satisfying such that

- $\omega(G) \leq \nu$;
- $\chi(H) \leq \tau_1$ for every induced subgraph $H$ of $G$ with $\omega(H) < \nu$; and
- $\chi^\rho(G) \leq \tau_2$

with sufficiently large chromatic number has an induced subgraph isomorphic to an $(\geq \ell)$-subdivision of $H$. Then $H$ is pervasive in the class of all graphs.

**Proof.** For $\ell, \nu \geq 0$, let $\mathcal{C}(\ell, \nu)$ be the class of all graphs $G$ such that

- no induced subgraph of $G$ is isomorphic to an $(\geq \ell)$-subdivision of $H$; and
- $\omega(G) \leq \nu$. 

29
To show that $H$ is pervasive in the class of all graphs, we must show that for all $\ell, \nu \geq 0$, there is an upper bound on the chromatic numbers of the graphs in $C_{\ell, \nu}$. For fixed $\ell$ we prove this by induction on $\nu$. Thus we may assume that there exists $\tau_1$ such that $\chi(H) \leq \tau_1$ for every graph in $C_{\ell, \nu-1}$. Consequently all graphs in $C_{\ell, \nu}$ satisfy the first two bullets in the theorem. Choose $\rho$ as in the theorem.

For each $\tau_2 \geq 0$, from the hypothesis there is an upper bound $\phi(\tau_2)$ on the chromatic number of the graphs in $C_{\ell, \nu}$ with $\chi^\rho(G) \leq \tau_2$; and we can choose $\phi$ nondecreasing. Consequently $C_{\ell, \nu}$ is $\rho$-controlled. By 1.5, $H$ is pervasive in $C_{\ell, \nu}$. Since no graph in $C_{\ell, \nu}$ contains an induced subgraph which is an $(\geq \ell)$-subdivision of $H$, it follows that there is an upper bound on the chromatic number of the graphs in $C_{\ell, \nu}$. This completes the induction, and hence proves 10.1.

Thus, if $H$ is a tree of chandeliers for which we can show that the hypothesis of 10.1 holds, then $H$ is pervasive. We have shown this for a few small graphs, but not yet (for instance) for the graph obtained from a triangle by adding two leaves to each of its three vertices. It is not worth listing here all the little cases we can do. For the moment, let us just do an easy one (which nevertheless considerably extends 1.2), a restatement of 1.10:

**10.2** For all $n \geq 0$, the complete bipartite graph $K_{2,n}$ is pervasive in the class of all graphs.

**Proof.** We may assume that $n \geq 2$. Let $\ell \geq 1$ and $\nu, \tau_1 \geq 0$, and let $C$ be the class of graphs $G$ such that

- no induced subgraph of $G$ is an $(\ell)$-subdivision of $K_{2,n}$;
- $\omega(G) \leq \nu$;
- $\chi(H) \leq \tau_1$ for every induced subgraph $H$ of $G$ with $\omega(H) < \nu$.

By 10.1, it suffices to prove that for some $\rho \geq 2$ and all $\tau_2 \geq 0$, every graph in $C$ with $\chi^\rho(G) \leq \tau_2$ has bounded chromatic number.

Let $\rho = \ell + 2$; we will show that this satisfies the theorem. For let $\tau_2 \geq 0$, and let $G \in C$ satisfy $\chi^\rho(G) \leq \tau_2$. Let $\ell = R(9, \max(\nu + 1, n + 1), 20)$; we will show that $\chi(G) \leq 2^\ell \tau_2$. For suppose not.

Choose a component $C_1$ of $G$ with maximum chromatic number, and choose $z_1 \in V(C)$. Then there is a number $k_1$ such that the set $X_1$ of vertices in $C_1$ with distance exactly $k_1$ from $z_1$ has chromatic number at least $\chi(G)/2$. Let $C_2$ be a component of $G[X_1]$ with maximum chromatic number, and choose $z_2 \in C_2$; then similarly, there is a number $k_2$ such that the set of vertices in $C_2$ with distance (in $G|C_2$) exactly $k_2$ from $z_2$ has chromatic number at least $\chi(X_1)/2 \geq \chi(G)/4$. By repeating this $t$ times, we obtain:

- $t$ numbers $k_1, \ldots, k_t \geq 0$;
- $t + 1$ connected subsets $C_1, \ldots, C_t, C_{t+1}$ of $V(G)$, with $C_j \subseteq C_i$ for $1 \leq i < j \leq t$, such that $\chi(C_{i+1}) \geq \chi(C_i)/2$ for $1 \leq i \leq t$;
- $t$ vertices $z_1, \ldots, z_t$, where $z_i \in C_i$, such that every vertex in $C_{i+1}$ has distance (in $G|C_i$) exactly $k_i$ from $z_i$. 

30
In particular, $\chi(C_{t+1}) \geq \chi(G)2^{-t} > \tau_2$. For each $i$, since $\chi(C_{t+1}) > \tau_2$, it follows that $k_i > \rho$, and in particular, $k_i > 2$. For $1 \leq i < j \leq t$, let $A_i$ be the set of vertices in $C_i$ with distance (in $G[C_i]$) at most $k_i - 2$ from $z_i$, and let $L_i$ be the set of vertices in $C_i$ with distance $k_i - 1$ in $G[C_i]$ from $z_i$. Thus $z_i \in A_i$. Since for $1 \leq i < j \leq t$, every vertex in $C_j$ has distance (in $G[C_i]$) exactly $k_i$ from $z_i$, it follows that:

(1) For $1 \leq i < j \leq t$, no vertex in $A_i$ has a neighbour in $A_j \cup L_j \cup C_j$.

(2) For $1 \leq i \leq t$, $G[A_i]$ is connected, and every vertex in $C_{i+1}$ has a neighbour in $L_i$, and every vertex in $L_i$ has a neighbour in $A_i$.

Choose $u \in C_{t+1}$. Since $\chi(C_{t+1}) > \tau_2$, there exists $v \in C_{t+1}$ such that the distance between $u, v$ in $G$ is at least $\rho + 1 = \ell + 3$. For $1 \leq i \leq t$, choose $u_i, v_i \in L_i$ adjacent to $u, v$ respectively, and choose an induced path $P_i$ with ends $u_i, v_i$ and all its interior vertices in $A_i$. This is possible by (2).

We see that the paths $P_1, \ldots, P_t$ are pairwise vertex-disjoint, and for each $i$ the path $u-u_i-P_i-v_i-v$ is induced. Also, the latter path has length at least $\rho + 1$, since the distance between $u, v$ is at least $\rho + 1$, and so $P_i$ has length at least $\rho - 1$.

For $1 \leq i < j \leq t$, there may be edges between $V(P_i)$ and $V(P_j)$; but by (1), no vertex of $P_i$ has a neighbour in $V(P_j)$ except possibly $u_i, v_i$.

For $1 \leq i < j \leq t$, let the type of $(i, j)$ be the pair $(x, y)$, where

- $x = 2$ if $u_i$ is adjacent to a vertex in the interior of $P_j$;
- $x = 1$ if $u_j$ is the only neighbour of $u_i$ in $P_j$;
- $x = 0$ if $u_i$ has no neighbours in $V(P_j)$.

and $y$ is defined similarly using $v_i, v_j$. (Note that $u_i, v_j$ are nonadjacent since the distance between $u, v$ is at least four, so $x$ is well-defined.)

There are only nine possible types, and since $t = R(9, \max(n+1, \nu + 1), 2, 0)$, there exists $I \subseteq \{1, \ldots, t\}$ with $|I| = \max(n+1, \nu + 1)$ such that all the pairs $(i, j)$ with $i, j \in I$ and $i < j$ have the same type $(x, y)$ say. It $x = 1$ then all the vertices $u_i(i \in I)$ are pairwise adjacent, which is impossible since $|I| > \nu$. So $x \in \{0, 2\}$ and similarly $y \in \{0, 2\}$. If $(x, y) = (0, 0)$, then there are no edges joining any two of the paths $P_i(i \in I)$, and together with $u, v$ they form an $(\geq \ell)$-subdivision of $K_{2,|I|}$, which is impossible. So we may assume that $x = 2$, exchanging $x, y$ if necessary. Choose $i_0 \in I$ minimum. Thus $u_{i_0}$ has a neighbour in the interior of $P_i$ for each $i \in I \setminus \{i_0\}$. If $y = 0$, for each $i \in I \setminus \{i_0\}$ let $Q_i$ be an induced path between $u_{i_0}$ and $v$ with interior in $V(P_i)$; these paths $Q_i(i \in I \setminus \{i_0\})$ each have length at least $\rho \geq \ell + 2$, and there are no edges between them, so they give an $(\geq \ell)$-subdivision of $K_{2,|I|-1}$, which is impossible. So $y = 2$. For each $i \in I \setminus \{i_0\}$ let $Q_i$ be an induced path between $u_{i_0}$ and $v_{i_0}$ with interior in $V(P_i)$; these paths $Q_i(i \in I \setminus \{i_0\})$ each have length at least $\rho - 1 \geq \ell + 1$, and there are no edges between them, so they give an $(\geq \ell)$-subdivision of $K_{2,|I|-1}$, which is impossible.

Thus $\chi(G) \leq 2^t \tau_2$, as claimed. This proves 1.10.
11 String graphs

A curve means a subset of the plane which is homeomorphic to the interval $[0,1]$. Given a finite set $C$ of curves in the plane, its intersection graph is the graph with vertex set $C$ in which distinct $S,T \in C$ are adjacent if $S \cap T \neq \emptyset$; and the intersection graphs of sets of curves are called string graphs. Every string graph can be realized by a set of piecewise linear curves, and in this paper, a string means a piecewise linear curve. In this section we prove that the class of string graphs is 3-controlled, and consequently the theorems of this paper can be applied to the class. The proof that they are 3-controlled is a modification and simplification of an argument of McGuinness [8], who showed that a similar statement holds for a triangle-free subclass of string graphs satisfying another condition that we omit.

Let $(v_1,\ldots,v_n)$ be a sequence of distinct vertices of a graph $G$. We say that $(v_1,\ldots,v_n)$ has the cross property if for all $h,i,j,k$ with $1 \leq h < i < j < k \leq n$, if $P,Q$ are paths of $G$ between $v_h,v_j$ and between $v_i,v_k$ respectively, then $V(P)$ is not anticomplete to $V(Q)$. We need the following.

11.1 Let $\Delta$ be a closed disc in the plane, and let $C$ be a finite set of strings all within $\Delta$. Let $C_1$ be the set of members of $C$ with nonempty intersection with the boundary of $\Delta$. Then $C_1$ can be ordered as $\{v_1,\ldots,v_n\}$ such that $(v_1,\ldots,v_n)$ has the cross property in the string graph of $C$.

Proof. Let $G$ be the string graph of $C$. Choose a point $d \in bd(\Delta)$ such that every member of $C_1$ contains a point of $bd(\Delta) \setminus \{d\}$, and for each $x \in C_1$ choose a point $f(x) \in x \cap (bd(\Delta) \setminus \{d\})$. Number $C_1$ such that the points $f(x)$ are in clockwise order, starting from $d$ and breaking ties arbitrarily. Let the numbering of $C_1$ be $\{v_1,\ldots,v_n\}$. If $1 \leq h < i < j < k \leq n$, and $P$ is a path of $G$ between $v_h,v_j$, then the union of the strings in $V(P)$ is an arcwise connected subset of $\Delta$, containing $f(v_h)$ and $f(v_j)$; and therefore includes a string $s$ with ends $f(v_h)$ and $f(v_j)$ (not necessarily in $C$) with $s \subseteq \Delta$. Similarly if $Q$ is between $v_i,v_k$, there is a string $t$ between $f(v_i)$ and $f(v_k)$. The strings $s,t$ intersect, and so one of the strings in $V(P)$ has nonempty intersection with one of the strings in $V(Q)$. This proves 11.1. \hfill \blacksquare

A homomorphism from a graph $H$ to a graph $G$ is a map $\eta : V(H) \rightarrow V(G)$, such that for all adjacent $u,v \in V(H)$, $\eta(u),\eta(v)$ are distinct and adjacent in $G$.

11.2 Let $G$ be a string graph. Then there is a graph $H$ and $V = \{v_1,\ldots,v_n\} \subseteq V(H)$, such that

- $(v_1,\ldots,v_n)$ has the cross property in $H$;
- every vertex in $V(H) \setminus V$ has a neighbour in $V$;
- there is a homomorphism from $H$ to $G$; and
- $\chi(H \setminus V) \geq \chi(G)/2$.

Proof. We may assume that $\chi(G) \geq 3$ for otherwise the result is trivial. Choose a component $D$ of $G$ with maximum chromatic number, and let $z \in D$. For $i \geq 0$ let $L_i$ be the set of vertices of $D$ with distance $i$ from $z$. Choose $k$ such that $\chi(L_k) \geq \chi(G)/2$. Thus $k \neq 0$, and if $k = 1$ then let $H$ be the subgraph induced on $L_0 \cup L_1$, and let $n = 1$ and $v_1 = z$, and the theorem holds. So we may assume that $k \geq 2$. Let $D'$ be a component of $G[L_k]$ with maximum chromatic number. The
union of the set of strings in $D'$ is a closed arcwise connected subset of the plane, say $S_1$; and also the union of the strings in $L_0 \cup \cdots \cup L_{k-2}$ is nonnull, closed and arcwise connected, say $S_2$; and $S_1 \cap S_2 = \emptyset$. Consequently there is a closed disc $\Delta$ in the plane disjoint from $S_2$ and with $S_1$ in its interior. Moreover, we can choose $\Delta$ such that for each string in $L_{k-1}$, its intersection with $\Delta$ is the disjoint union of a finite set of strings. Let $V$ be the set of all strings $s$ such that $s$ is a component of the intersection with $\Delta$ of a string in $L_{k-1}$, and let $H$ be the intersection graph of the set of strings $V \cup L_k$. For each $s \in V$, we claim that $s \cap bd(\Delta) \neq \emptyset$. For there exists $t \in L_{k-1}$ such that $s$ is a component of $t \cap \Delta$; then since $t$ is adjacent in $G$ to a vertex in $S_2$, and consequently $t \cap S_2 \neq \emptyset$, it follows that every component of $t \cap \Delta$ has nonempty intersection with $bd(\Delta)$, and in particular, $s \cap bd(\Delta) \neq \emptyset$ as claimed. The map $\eta : V(H) \to V(G)$ mapping each string in $V(H)$ to the string in $V(G)$ of which it is a component, is a homomorphism. Moreover, let $r \in V(H) \setminus V = L_k$; we claim that $r$ is adjacent in $H$ to a vertex in $V$. For let $t \in L_{k-1}$ be adjacent to $r$ in $G$; then $r \cap t \neq \emptyset$, and since $r \subseteq S_1$, it follows that $r \cap s \neq \emptyset$ for some $s \in V$. Consequently $r$ is adjacent in $H$ to a vertex in $V$. The result follows from 11.1. This proves 11.2.

Finally we need:

11.3 Let $H$ be a graph, let $V \subseteq V(H)$, and let $V = \{v_1, \ldots, v_n\}$ where $(v_1, \ldots, v_n)$ has the cross property in $H$. Assume also that every vertex in $V(H) \setminus V$ has a neighbour in $V$. Then

$$\chi^3(H) \geq \chi(H \setminus V)/20.$$

**Proof.** Let $\kappa = \chi^3(H)$, and suppose that $\chi(H \setminus V) > 20\kappa$. We may assume that $H$ is connected (by choosing a component of $H$ with maximum chromatic number, and working inside that). For each $i \geq 0$, let $L_i$ be the set of vertices of $H$ with distance exactly $i$ from $v_1$. Choose $k$ such that $\chi(L_k \setminus V) \geq \chi(H \setminus V)/2$. Thus $\chi(L_k \setminus V) > 10\kappa$. Since every vertex in $L_k$ has a neighbour in $V$, there are disjoint subsets $X_1, \ldots, X_n$ of $L_k \setminus V$ with union $L_k \setminus V$, such that every vertex in $X_i$ is adjacent to $v_i$ for $1 \leq i \leq n$. Consequently $\chi(X_i) \leq \kappa$ for $1 \leq i \leq n$.

(1) There exist $a, b, c, d$ with $1 \leq a < b < c < d \leq n$, such that there is a path of length three between $v_a, v_d$, and both its internal vertices belong to $L_k \setminus V$, and the subgraph of $H$ induced on $\bigcup_{b \leq i \leq c} X_i$ has chromatic number more than $4\kappa$.

For $0 \leq h \leq j \leq n$, let $Y(h, j) = \bigcup_{h \leq i \leq j} X_i$. Let $i_0 = 0$. Inductively, having defined $i_{j-1}$, choose $i_j$ with $i_{j-1} \leq i_j \leq n$ minimal such that $\chi(Y(i_{j-1}, i_j)) > 4\kappa$, if such a choice is possible; and otherwise let $i_j = n$ and stop. Let this process stop with $j = t$ and $i_t = n$ say. For $1 \leq j < t$, the minimality of $i_j$ implies that $\chi(Y(i_{j-1}, i_j)) \leq 5\kappa$, since $\chi(X_i) \leq \kappa$. Also $\chi(Y(i_{j-1}, i_t)) \leq 4\kappa$ since the sequence stopped. Since each of $Y(i_0, i_1), Y(i_1, i_2), \ldots, Y(i_{t-1}, i_t)$ has chromatic number at most $5\kappa$, and $\chi(L_k \setminus V) > 10\kappa$, there exist $h, k$ with $1 \leq h \leq k \leq t$ and $h + 2 \leq k$ such that there is an edge between $Y_{i_{h-1}, i_h}$ and $Y_{i_{k-1}, i_k}$. Choose $j$ with $h < j < k$; then, taking $b = i_{j-1} + 1$ and $c = i_j$, and choosing $a \leq i_{j-1}$ and $d > i_j$ such that there is an edge between $X_a$ and $X_d$, this proves (1).

Choose $a, b, c, d$ as in (1), and let $Q$ be a path between $v_a, v_d$ of length three.

(2) For each $v \in \bigcup_{b \leq i \leq c} X_i$, there is a vertex $q$ of $Q$ such that the distance between $v, q$ is at most three.
Since \( v \in L_k \), there is a path \( P \) between \( v_1, v \) of length \( k \). Let its vertices be \( p_0-p_1-\cdots-p_k \) in order, where \( p_0 = v_1 \) and \( p_k = v \). Choose \( e \) with \( b \leq e \leq c \) such that \( v \) is adjacent to \( v_e \). Then there is a path of \( H \) between \( v_e, v_1 \) with interior included in \( V(P) \). By the cross property, there is a vertex \( q \in V(Q) \) that either belongs to \( V(P) \cup \{v_e\} \) or has a neighbour in \( V(P) \cup \{v_e\} \). Now since the interior vertices of \( Q \) belong to \( L_k \), it follows that for \( 0 \leq i \leq k-3 \), \( p_i \notin V(Q) \) and has no neighbour in \( V(Q) \). So \( q \) equals or is adjacent to one of \( p_{k-2}, p_{k-1}, p_k = v, v_e \). In each case the distance between \( v, q \) is at most three. This proves (2).

Since the subgraph of \( H \) induced on \( \bigcup_{b \leq i \leq c} X_i \) has chromatic number more than \( 4\kappa \), (2) implies that for one of the four vertices of \( Q \), say \( q \), \( \chi(N^3[q]) > \kappa \), a contradiction. Thus \( \chi(H \setminus V) \leq 20\kappa \). This proves 11.3.

From 11.2 and 11.3, we deduce:

**11.4** For every string graph \( G \), \( \chi(G) \leq 40\chi^3(G) \).

**Proof.** Let \( G \) be a string graph, and choose \( H \) and \( V \) as in 11.2. Thus \( \chi(H \setminus V) \geq \chi(G)/2 \). By 11.3, \( \chi^3(H) \geq \chi(H \setminus V)/20 \), and so \( \chi^3(H) \geq \chi(G)/40 \). But \( \chi^3(G) \geq \chi^3(H) \) since there is a homomorphism from \( H \) to \( G \). This proves 11.4.

In particular, the class of string graphs is 3-controlled. Since no string graph has an induced subgraph which is a proper subdivision of \( K_{3,3} \), 6.1 implies 1.7, which we restate:

**11.5** The class of string graphs is 2-controlled.

Consequently the theorems of this paper apply to string graphs, and in particular, 7.9 implies 1.8, which we restate:

**11.6** Let \( \nu \geq 0 \), and let \( H \) be a tree of lamps. Then there exists \( c \) such that every string graph with clique number at most \( \nu \) and chromatic number greater than \( c \) contains \( H \) as an induced subgraph.

## 12 Acknowledgement

We would like to thank Sean McGuinness for his advice on string graphs.
