Supporting Information

**ABSTRACT:** A selenolate-protected Ag–Pd alloy cluster was synthesized using a one-pot solution-phase route. The crude product upon chromatographic analyses under optimized conditions gave three distinct clusters with unique optical features. One of these exhibits a molecular peak centered at m/z 2839, in its negative ion mass spectrum assigned to Ag4Pd3(SePh)12, having an exact match with the corresponding calculated spectrum. Tandem mass spectrometry of the molecular ion peak up to MS9 was performed. Complex isotope distributions in each of the mass peaks confirmed the alloy composition. We find the Ag4Pd3 core to be highly stable. The composition was further supported by scanning electron microscopy, energy-dispersive spectroscopy, and X-ray photoelectron spectroscopy.

**SECTION:** Physical Processes in Nanomaterials and Nanostuctures

**N**oble metal clusters with monolayer protection are becoming one of the most fascinating areas of contemporary chemical research. They have been used in several applications5–12 because of their unique optical properties, especially photoluminescence.13–16 Among them, gold clusters have been studied extensively. Crystal structures of several gold clusters such as Au21,17 Au23,18 Au25,19 Au28,19 Au30,20 Au32,21 Au34,22 and Au36,23 have been reported. Silver clusters have been studied to a lesser extent,24–26 although reports exist on Ag27,27 Ag29,28 Ag30,29 Ag32,30 Ag34,31 Ag36,32,33 and Ag38,34 with detailed characterization, dominated by mass spectrometry. Reports of mixed ligand (phosphine and thiol)-protected Ag29,29 Ag30,30 and Ag32,30 are also there. Recently, crystal structure of the very first complete thiol-protected core, namely, Ag4Pd3,35,36 has been solved. A limited number of studies exist on other metal clusters like Pt,37 Cu,38 and so on. However, synthesis of atomically precise alloy clusters of various compositions is a challenge, and very few reports exist in the literature.39–41 Examples include PdAu24,42 Pd2Au36,43 Pd3Au44,44 and Ag–Au,45 all of which have thiol protection. Selenolate-protected single metal clusters such as Au24,46 Au26,47 Au28,48 Au30,49 and Ag34,33 have been reported, whereas only one alloy, namely, Cu2Au25 (n = 1–9),50 is known with such monolayers. So far, to the best of our knowledge, there is no report on Ag–Pd alloy clusters.

We report the very first selenolate protected Ag–Pd alloy cluster. The crude cluster was synthesized from silver trifluorocetate(s) and sodium tetracholopalladate(s) in the presence of benzeneselenol (l) (details are in Supporting Information 1). Solid NaBH₄ was added, and stirring was continued. The color change of orange to yellowish brown indicated the conversion of selenolates to clusters (Figure S2 in the Supporting Information). Several analytical methods were used to characterize the clusters (Supporting Information 1).

The crude clusters show the presence of molecule-like features in absorption spectroscopy (Figure 1). The spectrum gives peaks near 400 (3.1), 381 (3.25), 326 (3.8), 282 (4.4), and 248 (4.99) nm (eV) and a small hump at 590 (2.1) nm (eV). The crude cluster was subjected to HPLC for purification using acetonitrile as the solvent in the isocratic mode. Several parameters such as the pump pressure, solvents, flow rate, temperature, and so on were optimized to achieve the isolation process. Slower flow rate leads to longer time for the cluster to come out, but isolation becomes easier as expected (Figure S3 in the Supporting Information). The best separation was observed with 0.25 mL/min flow rate at room temperature. The corresponding chromatogram gives three well-separated peaks (Figure 1) at retention times of 6.44, 7.69, and 10.70 min, which have been marked as clusters 1, 2, and 3, respectively. Characteristic UV/vis features were observed for different isolated species (Figure 1a and Figure S4 in the Supporting Information). Cluster 1 shows peaks at 3.27 (379), 3.94 (315), 4.4 (282), and 4.8 (258) eV (nm) and a small hump at 1.93 eV (642 nm), whereas cluster 2 has peaks at 3.1 (400), 3.8 (326), 4.47 (277), and 4.9 (253) eV (nm) and a small hump at 2.1 (590) eV (nm). Compared with clusters 1 and 2, cluster 3 shows a different nature, and it has multiple humps at 1.9 (653), 2.8 (443), 3.3 (376), 3.8 (326), 4.4 (282), 5.0 (253), 5.5 (225), and 6.0 (185) nm.

Thermal fragmentation studies of the clusters with mass to charge ratios (m/z) 2839 along with some fragments at m/z 1431, 1600, and 2204, which have been assigned as \[\text{Ag}_5\text{Pd}_4\text{(SePh)}_{12}\]. The ESI MS of the crude cluster was analyzed in the negative ion mode for structural elucidation. Tandem mass spectra were performed with the fragment at m/z 2839 as the parent ion. Comparison with the corresponding calculated spectrum shows an exact match with the fragment at m/z 2839, which is the molecular ion and the cluster in solution state itself. All of these suggest that the peak at m/z 2839 is very likely to be an intact ion as no other ion was seen in the higher mass region, until m/z 2500. Spectrum was also measured at various ESI conditions, which ensured that no other higher mass molecules are present in the solution. No higher charge state was detected. All of these suggest that the peak at m/z 2839 is the molecular ion and the cluster in solution state itself is negatively charged. We have focused only on cluster 2 in this report because it gives a well-defined and fully assignable mass spectrum. Subsequent studies were done only on this cluster. The cluster is stable for more than one month under ambient conditions.

For a detailed understanding of the fragmentation pattern and for structural elucidation, tandem mass spectra were measured for each peak present in the mass spectrum of cluster 2. The most intense and closest peak obtained in MS\(^2\) was subjected to further fragmentation to get the MS\(^3\) data, and subsequent MS\(^4\) measurements were performed until reasonable intensities were seen. Although there is no particular pattern followed for each fragmentation, we could see four different types of losses overall; they correspond to −SePh, −Ph, Ag, and Pd. Sometimes, simultaneous losses of −SePh and −Ph as well as Ag/Pd and −SePh were seen. The MS/MS data for the peak at m/z 2839 shows (Figure 3) an initial loss of m/z 312, followed by a loss of m/z 624 that correspond to 2 and 4 SeR (R = C\(_6\)H\(_5\)) moieties, respectively. MS\(^3\) was performed with the fragment at m/z 2525 (assigned to Ag\(_3\)Pd\(_4\)Se\(_8\)), as previously discussed. Interestingly, all of the fragments seen in Figure 2 for the parent clusters are also consistent with the corresponding photographs of the cluster solutions (marked as i’ and ii’, respectively). The assignment can be made based on the characteristic color, which makes them distinguishable from each other as well as from the crude cluster (Figure 1a and Figure S4 in the Supporting Information).

Electrospray ionization mass spectrometry (ESI MS) is known to be the best tool for precise characterization of clusters. The assignment can be made based on the molecular ion peak and various charged species of the parent ion. Observation of good isotopic distribution can also be a strong support for predicting the elements present in the spectra. For example, the stable Au\(_{25}\)(SR)\(_{18}\) cluster shows a fragment in the mass spectrum due to the Au\(_4\)(SR)\(_3\) loss. Even the stable Ag\(_{44}\)(SR)\(_{30}\) cluster, for which the crystal structure was determined recently, shows several fragments due to Ag\(_n\)(SR)\(_n\) losses. It is important to mention here that for this cluster the molecular peak with 4− charge has much lower intensity compared with the fragments seen in the lower mass range (m/z 100–1500). Au\(_{25}\) and Ag\(_{44}\) are the most stable clusters reported so far, for the case of gold and silver, respectively. They have closed-shell electronic configuration consisting of 8 and 18 number of electrons. These clusters show stable species in the gas phase along with their fragments. So, it is clear that fragmentation is likely under ESI conditions for clusters. However, the peak at m/z 2839 is very likely to be a multicharged species due to Ag/Pd and SePh losses, respectively. Inset: (a) Calculated (red trace) and experimental (black trace) mass spectra of \[\text{Ag}_5\text{Pd}_4\text{(SePh)}_{12}\]. (b) Cartoon representation of the Ag\(_5\)Pd\(_4\) cluster with its ligands.

Figure 1. HPLC chromatogram of the crude cluster in acetonitrile at room temperature (30 °C) using the isocratic mode. Flow rate was optimized at 0.25 mL/min. The UV/vis detector was used for analysis. Three distinct peaks correspond to clusters 1–3. Inset: (a) UV/vis spectra of as-synthesized (i) crude and (ii) cluster 2; inset of inset shows the corresponding photographs of the cluster solutions (marked as i’ and ii’, respectively). (b) HRTEM image of cluster 2. (c) Size distribution. A few particles are marked with yellow circles.

Figure 2. ESI MS data of cluster 2. All peaks are assigned to their compositions. We believe that the peak at m/z 2839 is the molecular ion and others are fragments due to the following reasons. Even when the cluster is stable, fragmentation is common under ESI conditions. For example, the stable Au\(_{25}\)(SR)\(_{18}\) cluster shows a fragment in the mass spectrum due to the Au\(_4\)(SR)\(_3\) loss. Even the stable Ag\(_{44}\)(SR)\(_{30}\) cluster, for which the crystal structure was determined recently, shows several fragments due to Ag\(_n\)(SR)\(_n\) losses. It is important to mention here that for this cluster the molecular peak with 4− charge has much lower intensity compared with the fragments seen in the lower mass range (m/z 100–1500). Figure 3. MS/MS data of m/z 2839. Repeated MS/MS was done with the most intense fragments closer to the parent ion (marked by gray star in all traces, except the last one). Multiple losses were seen for each case, and they are indicated on the arrow. Up to MS5 was achievable with reasonable intensity. Spectra have been shifted vertically for clarity.

![Figure 3](image)

Figure 4. MS/MS spectrum showing a fragment derived from m/z 2839. A* and B are the MS/MS data derived from m/z 2839 with the isotope width of 30 and 1, respectively. Trace B is composed of a number of MS/MS spectra. Each peak selected for MS/MS studies (m/z 2823 to 2853, shown on top of the spectra) and the resulting fragments is shown using specific colors.

![Figure 4](image)
structures are also possible. It was also shown that silver can coordinate with three sulfur ligands. It is important to note that Pd(II) can coordinate with four ligands. So, it is not unusual to see the existence of such clusters.

HRTEM of cluster 2 (Figure 1b) shows the presence of highly monodisperse clusters with an average diameter of 0.85 nm (Figure 1c). Complete absence of bigger particles suggests the high purity of the cluster. The composition was further supported with SEM/EDAX data, where the Ag:Pd:Se ratio matches well with the calculated one (Figure S10 in the Supporting Information). Precise composition was already confirmed by HRESI MS data. The EDAX data were to support the suggestion. XPS survey spectrum shown peaks (Figure S11A in the Supporting Information) for all expected elements. The Ag 3d5/2 peak could be fitted to two components (Figure S11B in the Supporting Information) with maxima at 367.5 and 368.0 eV binding energy (BE). The Pd 3d3/2 peak appeared at a BE of 336.6 eV, which lies in between the values of Pd(II) and Pd(0) (Figure S11D in the Supporting Information).54 The Se 3d peak came at 54.3 eV BE (Figure S11C in the Supporting Information), as expected for the selenolate species. It is important to mention here that Ag(0) and Ag(I) have only 0.5 eV58 difference in binding energy, so it is difficult to predict the exact charge on silver from photoemission data. However, the data suggest that Ag is present in two oxidation states with 3:2 ratio, whereas Pd is closer to its Pd(II). Although it is difficult to propose a structure based on this information alone, it is likely that distinct silver forms exist in the cluster.

Outer electron count of the Ag5Pd4(SePh)12 system would suggest a 33 electron species (taking s1 and d9 valence shells for Ag and Pd, respectively, and subtracting one electron each for the ligands, which form the selenolates, and the entity as a whole may be stabilized by a negative change, making the system a closed shell. This may be the reason for the larger intensity of the negative ion. However, a clear rationalization of the data would require the structure.

In summary, selenolate-protected Ag–Pd alloy clusters have been synthesized using one-pot solution-phase synthesis. The crude cluster was purified using HPLC, which gave three different clusters with characteristic optical absorption spectra. ESI MS data suggest that only cluster 2 shows interesting features for which the molecular ion peak appeared at m/z 2839, assigned as [Ag4Pd4(SePh)11]−. Systematic MS/MS was carried out for the molecular ion peak as well as other fragments. Interestingly, up to MS9 is achievable with reasonable intensity, which is the maximum limit for a monolayer-protected cluster reported so far. The result is also supported by several other characterization measurements. It is hoped that single-crystal studies will be possible once its stability is improved.

**EXPERIMENTAL METHODS**

Materials used in the synthesis are listed in the Supporting Information.

**Synthesis of Ag5Pd4 Cluster.** One-pot solution phase route was followed to synthesize the crude cluster. Silver trifluoroacetate (10 mg) and sodium tetrachloroplatinate (7 mg) were dissolved in 36 mL of acetonitrile taken in a conical flask and kept for stirring. Then, 5 μL of benzeneselenol was added and the color changed from faint yellow to orange, confirming the formation of selenolate. Finally, 10.2 mg of sodium borohydride (s) was added and stirring was continued for 2 h. The color changed to yellowish brown, which confirmed the formation of the crude cluster. It was then centrifuged at 5000 rpm, and the centrifugate was collected for HPLC purification.

Materials, methods, and computational details are given in Supporting Information 1.
