Stackelberg Solutions to Noncooperative Two-Level Nonlinear Programming Problems through Evolutionary Multi-Agent Systems

Masatoshi Sakawa, Hideki Katagiri and Takeshi Matsui
Faculty of Engineering, Hiroshima University
Japan

1. Introduction

In the real world, we often encounter situations where there are two or more decision makers in an organization with a hierarchical structure, and they make decisions in turn or at the same time so as to optimize their objective functions. Decision making problems in decentralized organizations are often modeled as Stackelberg games (Simaan & Cruz Jr., 1973), and they are formulated as two-level mathematical programming problems (Shimizu et al, 1997; Sakawa & Nishizaki, 2009). In the context of two-level programming, the decision maker at the upper level first specifies a strategy, and then the decision maker at the lower level specifies a strategy so as to optimize the objective with full knowledge of the action of the decision maker at the upper level. In conventional multi-level mathematical programming models employing the solution concept of Stackelberg equilibrium, it is assumed that there is no communication among decision makers, or they do not make any binding agreement even if there exists such communication. Computational methods for obtaining Stackelberg solutions to two-level linear programming problems are classified roughly into three categories: the vertex enumeration approach (Bialas & Karwan, 1984), the Kuhn-Tucker approach (Bard & Falk, 1982; Bard & Moore, 1990; Bialas & Karwan, 1984; Hansen et al, 1992), and the penalty function approach (White & Anandalingam, 1993). The subsequent works on two-level programming problems under noncooperative behavior of the decision makers have been appearing (Nishizaki & Sakawa, 1999; Nishizaki & Sakawa, 2000; Gumus & Floudas, 2001; Nishizaki et al., 2003; Colson et al., 2005; Faisca et al., 2007) including some applications to aluminium production process (Nicholls, 1996), pollution control policy determination (Amouzegar & Moshirvaziri, 1999), tax credits determination for biofuel producers (Dempe & Bard, 2001), pricing in competitive electricity markets (Fampa et al, 2008), supply chain planning (Roghanian et al., 2007) and so forth. However, processing time of solution methods for noncooperative two-level linear programming problems, for example, Kth Best method by Bialas et al. (1982) and Branch-and-Bound method by Hansen et al. (1992), may exponentially increases at worst as the size of problem increases since they are strict solution methods based on enumeration. In order to obtain the (approximate) Stackelberg solution with a practically reasonable time, approximate solution methods were presented through genetic algorithms (Niwa et al., 1999) and particle swarm optimization (PSO) (Niwa et al., 2006).
As one of the most promising approximate solution methods, Socha et al. (2002) proposed a fast computational method through an evolutionary multi-agent system (EMAS) for obtaining (approximate) Pareto optimal solution sets for multiobjective programming problems. However, there is no study on the EMAS-based method for solving two-level nonlinear programming problems.

In this chapter, we propose an efficient EMAS-based computational method for obtaining (approximate) Stackelberg solutions to two-level nonlinear programming problems.

2. Two-level programming problems and solution concepts

In this chapter, we consider two-level programming problems formulated as follows:

\[
\begin{align*}
\text{minimize } & f_1(x_1, x_2) \\
\text{where } & x_2 \text{ solves } f_2(x_1, x_2) \\
\text{subject to } & g_i(x_1, x_2) \leq 0, \quad i = 1, 2, \ldots, m
\end{align*}
\]

where \(x_1\) is an \(n_1\) dimensional decision variable column vector for the DM at the upper level (DM1), \(x_2\) is an \(n_2\) dimensional decision variable column vector for the DM at the lower level (DM2), \(f_1(x_1, x_2)\) is the objective function for DM1, \(f_2(x_1, x_2)\) is the objective function for DM2 and \(g_i(x_1, x_2), i = 1, 2, \ldots, m\) are constraint functions. In general, \(f_l(\cdot), l = 1, 2\) and \(g_i(\cdot), i = 1, 2, \ldots, m\) are nonlinear. In (1), if the DM at the upper level (DM1) adopts a decision \(x_1\), the DM at the lower level (DM2) is supposed to select a decision to minimize \(f_2(\cdot)\) in the feasible region of (1) under the DM1's decision, \(\hat{x}_2(\hat{x}_1)\), called a rational reaction. Then, the optimal solution (Stackelberg solution) to (1) is the point \((x_1^*, x_2^*(x_1^*))\) which minimizes \(f_1(\cdot)\) in the inducible region (IR) which is the set of points \((\hat{x}_1, \hat{x}_2(\hat{x}_1))\) for all possible decisions \(\hat{x}_1\). Figure 1 illustrates an example of a Stackelberg solution for a two-level linear programming problem.
3. EMAS for two-level programming problems

In this section, we outline the framework of a computational method through EMAS for obtaining Stackelberg solutions to two-level programming problems. In general, EMAS-based methods consist of \( N \) agents \( a_r, r = 1, 2, \ldots, N \), each of which is characterized by some attributes, i.e., the current position \((x_{r1}, x_{r2})\), the upper level objective function value \( f_1(x_{r1}, x_{r2})\), the lower level objective function value \( f_2(x_{r1}, x_{r2})\), the upper level energy \( e_{rU} \) and the lower level energy \( e_{rL} \). In the EMAS-based method, the attributes of agents are updated through the evolutionary process with some operations like energy exchange, reproduction and move.

First, carry out the search to the direction of improving the lower level objective function by moving each agent toward IR. To be more specific, in the upper level decision variable space, if there exists at least one agent in the neighborhood of each agent \( a_r \), select one of agents, \( a_r' \), as a communicating opponent, and compare the lower level objective function value of \( a_r \) with that of \( a_r' \). Then, the superior agent gains the lower level energy from the inferior one. The inferior agent is killed if the lower level energy of it becomes empty. Otherwise, it is moved according to some rule whose details are described later in Section 4. If there exists no agent in the neighborhood of \( a_r \), move \( a_r \) to the position where the lower level objective function value becomes better by changing \( x_{r2} \).

Next, carry out the search to the direction of improving the upper level objective function by moving each agent near IR toward a Stackelberg solution. For each agent \( a_r \), after selecting an agent, \( a_{r''} \), which is the nearest agent around IR as a communicating opponent, compare the upper level objective function value of \( a_r \) with that of \( a_{r''} \). Then, the superior agent gains the upper level energy from the inferior one. The inferior agent is not killed even if its lower level energy of it becomes empty. It gains the same amount of the upper level energy as the initial value. This supplement is done to maintain the number of agents with nonzero upper level energy. After exchanging the upper level energies between the superior and inferior agents, if the upper level energy of the inferior agent is sufficiently large, generate a new agent in the direction from the inferior one to the superior one.

By repeating these procedures, agents with large upper level objective function values congregate around IR, which means the current position of the agent with the largest upper level objective function value can be regarded as the (approximate) Stackelberg solution.

The procedure is summarized as follows.

**Step 1.** Generate \( N \) agents \( a_r, r = 1, 2, \ldots, N \) at random.

**Step 2.** Let \( T := 1 \).

**Step 3.** Let \( r := 1 \).

**Step 4.** For the \( r \)th agent \( a_r \), carry out the search to the direction of improving the lower level objective function value in order to move the current position of the agent toward IR.

**Step 5.** If the lower level energy of the \( r \)th agent \( a_r \) is greater than a threshold, i.e., the current position of the agent is regarded as being in IR, carry out the search to the direction of improving the upper level objective function value so that the agent is moved toward the Stackelberg solution.

**Step 6.** If \( r = N \), go to step 7. Otherwise, let \( r := r + 1 \) and return to step 4.

**Step 7.** If \( T = T_{\text{max}} \) terminate the procedure and the current best solution is regarded as a Stackelberg solution. Otherwise, let \( T := T + 1 \) and return to step 3.
4. EMAS for two-level nonlinear programming problems

This section devotes to introducing some basic ideas of a new EMAS for two-level nonlinear programming problems. In applying the original EMAS directly to the nonlinear case, there often occur two problems; one is that it is difficult to obtain feasible initial agents generated randomly in step 1, and the other is that the judgment of the existence of an agent around IR by the amount of the lower level energy is insufficient in most cases since the shape of IR for nonlinear cases is fairly complicated in general than that for the linear case.

In order to resolve the former problem, we incorporate the idea of homomorphous mapping used in (Koziel & Michalewicz, 1999) into the proposed method in order to generate feasible initial agents. In addition, in order to widen the search area, we permit the reproduction in the infeasible region together with the search of the infeasible region by infeasible agents.

On the other hand, for tackling the latter problem, we utilize the Kuhn-Tucker condition of problem (2), which is the necessary condition for the current position to be in IR, in order to obtain the rational reaction \( \bar{x}_2(\bar{x}_1) \) corresponding to \( \bar{x}_1 \) for the purpose of more accurately check whether an agent with the current position \((x_1, x_2)\) exists around IR or not.

\[
\begin{align*}
\text{minimize} & \quad f_2(\bar{x}_1, x_2) \\
\text{subject to} & \quad g_i(\bar{x}_1, x_2) \leq 0, \quad i = 1, 2, \ldots, m
\end{align*}
\]  

The Kuhn-Tucker condition of (2) is expressed as follows.

\[
\nabla f_2(\bar{x}_1, x_2^*) + \sum_{i=1}^{m} \lambda_i^* \nabla g_i(\bar{x}_1, x_2^*) = 0, \lambda^* \geq 0,
\]

\[
g_i(\bar{x}_1, x_2^*) \leq 0, \lambda_i^* g_i(\bar{x}_1, x_2^*) = 0, i = 1, 2, \ldots, m
\]

It should be noted here that the best position \((\hat{x}_1, \hat{x}_2)\) obtained through the search by EMAS does not always exist in IR even if it satisfies the Kuhn-Tucker condition. In order to find a rational reaction for the upper level decision \(\hat{x}_1\) of the best solution, the following problem with respect to the lower level objective function is solved.

\[
\begin{align*}
\text{minimize} & \quad f(\hat{x}_1, x_2) \\
\text{subject to} & \quad g_i(\hat{x}_1, x_2) \leq 0, \quad i = 1, 2, \ldots, m
\end{align*}
\]  

Since (3) is a single-objective nonlinear programming problem, we can solve the problem by using an approximate solution method based on PSO (Matsui et al, 2007) to check whether the (approximate) optimal solution \((x_2')\) is equal to \(\hat{x}_2\) or not. If \((x_2') = \hat{x}_2\), we can regard \((\hat{x}_1, \hat{x}_2)\) as the (approximate) Stackelberg solution since it exists in IR. Otherwise, repeatedly check whether the current position of an agent satisfying Kuhn-Tucker condition exists in IR or not in the same manner mentioned above in order of the quality of the upper level objective function value. If an agent whose current position exists in IR, the position is regarded as the (approximate) Stackelberg solution.
5. Detailed procedure of the proposed EMAS

In this section, we describe the details of the computational procedures in the proposed EMAS for obtaining (approximate) Stackelberg solutions to noncooperative two-level nonlinear programming problems.

In the proposed EMAS-based method, we use $N$ agents $a_r$, $r=1, 2, ..., N$, each of which is characterized by some attributes, i.e., the current position $(x_{i1}, x_{i2})$, the upper level objective function value $f_1(x_{i1}, x_{i2})$, the lower level objective function value $f_2(x_{i1}, x_{i2})$, the energy $e$, and the agent state variable $k_r$. If Kuhn-Tucker condition is satisfied for the $r$th agent $a_r$ whose current position is in the feasible region, let $k_r=1$. If not, let $k_r=0$. For agents in the infeasible region, let $k_r<0$.

The procedure of the proposed EMAS-based method is summarized as follows.

**Step 1.** Generate $N$ agents $a_r$, $r=1, 2, ..., N$ by using the homomorphous mapping (Koziel & Michalewicz, 1999).

**Step 2.** Let $T:=1$.

**Step 3.** Let $r:=1$.

**Step 4.** If $k_r=0$, go to step 5. If $k_r=1$, go to step 6. If $k_r<0$, go to step 8.

**Step 5.** Carry out the search to the direction of improving the lower level objective function value. To be more specific, for the $r$th agent $a_r$, choose an agent $a_{r'}$ randomly. Then, compare $f_2(x_{r1}, x_{r2})$ with $f_2(x_{r'1}, x_{r'2})$. If $f_2(x_{r1}, x_{r2}) < f_2(x_{r'1}, x_{r'2})$, let $x_{p2} := x_{r2}$ and $x_{r'2} := x_{r2}$. Otherwise, let $x_{p2} := x_{r2}$ and $x_{r'2} := x_{r2}$.

Then, update $x_{p2}$ by the following scheme:

$$x_{p2} := x_{p2} + 2R(x_{p2} - x_{r'2})$$  \hspace{1cm} (4)

where $R$ is a uniform random number in $[0,1]$. Repeat the comparison between $f_2(x_{r1}, x_{r2})$ and $f_2(x_{r'1}, x_{r'2})$ and the update of $x_{p2}$ $n$ times. Let the final $x_{p2}$ be $x_{r2}$. If the current position of $a_r$ satisfies Kuhn-Tucker condition, let $k_r:=1$ and go to step 6. Otherwise, go to step 9.

**Step 6.** If $k_r=1$, carry out the search to the direction of improving the upper level objective function value. To be more specific, choose an agent $a_{r''}$ which satisfies Kuhn-Tucker condition at random as a comparing opponent and compare the upper level objective function value of $a_r$ with that of $a_{r''}$. Then, the superior agent gains the energy from the inferior one. Let the superior agent denote $a_{r''}$ and the inferior one denote $a_r$. If the inferior agent is killed by the disappearance of energy, go to step 7. Otherwise, go to step 9.

**Step 7.** Carry out the reproduction of the killed agent. Then, reproduce $a_r$ with the current position which is determined as:

$$(x_{i1},x_{i2}) := (x_{i1},x_{i2}) + 2R((x_{r'-1},x_{r'-2}) - (x_{r'-1},x_{r'-2})).$$  \hspace{1cm} (5)

where $R$ is a uniform random number in $[0,1]$. If the current position of the reproduced $a_r$ is infeasible, let $k_r:= -1$ and go to step 8. Otherwise, let $k_r:=0$ and go to step 9.

**Step 8.** Carry out the search in the infeasible region. If $-t_1 \leq k_r < 0$, go to substep 8-1. If $-t_2 \leq k_r < -t_1$, go to substep 8-2. If $kr = -t_2$, go to substep 8-3. Here, let $0 < t_1 < t_2$.

**Substep 8-1:** Let an agent with the current position $(x_{i1}, x_{i2}, ..., x_{i_r'}, ..., x_{i_r}, n_2)$ denote $a_{r'}$. Here, $r'$ is randomly chosen from among $\{1, 2, ..., N\}$ and $i$ is randomly
chosen from among \{1, 2, \ldots, n_1+n_2\}. Compare \(f_1(x_{a_1}, x_{a_2})\) with \(f_2(x_{r_1}, x_{r_2})\). Let the superior agent and the inferior one denote \(a_s\) and \(a_i\), respectively. Then, update \((x_{a_1}, x_{a_2})\) by the following scheme:

\[
(x_{a_1}, x_{a_2}) = (x_{a_1}, x_{a_2}) + 2R((x_{a_1}, x_{a_2}) - (x_{r_1}, x_{r_2}))
\]  

(6)

where \(R\) is a uniform random number in \([0,1]\). Repeat the comparison between \(f_1(x_{a_1}, x_{a_2})\) and \(f_1(x_{r_1}, x_{r_2})\) and the update of \((x_{a_1}, x_{a_2})\) \(n'\) times. Let the final \((x_{a_1}, x_{a_2})\) be \((x_{a_1}, x_{a_2})\). If \((x_{a_1}, x_{a_2})\) is feasible, let \(k:=0\). Otherwise, let \(k:=k-1\). Go to step 9.

**Substep 8-2:** Choose an agent \(a_r\) randomly. Compare \((x_{a_1}, x_{a_2})\) with \((x_{r_1}, x_{r_2})\) using the following function

\[
h(x_1, x_2) = \sum_{i=1}^{m} g_i(x_1, x_2), 0 > 0
\]

which is the degree of violation of the constraints. Let the superior position denote \((x_{a_1}, x_{a_2})\) and the inferior one denote \((x_{r_1}, x_{r_2})\). Then, update \((x_{a_1}, x_{a_2})\) by the following scheme:

\[
(x_{a_1}, x_{a_2}) = (x_{a_1}, x_{a_2}) + 2R((x_{a_1}, x_{a_2}) - (x_{r_1}, x_{r_2}))
\]

where \(R\) is a uniform random number in \([0,1]\). Repeat the comparison between \(h(x_{a_1}, x_{a_2})\) and \(h(x_{r_1}, x_{r_2})\) and the update of \((x_{a_1}, x_{a_2})\) \(n''\) times. Let the final \((x_{a_1}, x_{a_2})\) be \((x_{a_1}, x_{a_2})\). If \(h(x_{a_1}, x_{a_2})\) is feasible, let \(k:=0\). Otherwise, let \(k:=k-1\). Go to step 9.

**Substep 8-3:** Choose an agent \(a_r\) whose current position is feasible randomly, and move \(a_r\) to the feasible region by the bisection method between \(a_r\) and \(a_s\). Go to step 9.

**Step 9.** If \(r = N\), go to step 10. Otherwise, let \(r:=r+1\) and return to step 4.

**Step 10.** If \(T = T_{max}\) go to step 11. Otherwise, let \(T:=T+1\) and return to step 3.

**Step 11.** Check whether the current position of the best agent exists in IR or not by solving (3) through the revised PSO method (Matsui et al., 2007), which is one of most promising solution methods for nonlinear programming problems. If the current position of the best agent exists in IR, we can regard it as the (approximate) Stackelberg solution. Otherwise, repeatedly check whether the current position of an agent satisfying Kuhn-Tucker condition exists in IR or not in the same manner mentioned above in order of the quality of the upper level objective function value. If an agent whose current position satisfies Kuhn-Tucker condition and exists in IR, the position is regarded as the (approximate) Stackelberg solution, and the solution procedure is terminated.

6. Numerical examples

In order to investigate the efficiency of the proposed method, we conduct some numerical experiments.

First, we consider a two-level nonlinear programming problem with 4 decision variables and 8 constraints (P1) and one with 6 decision variables and 10 constraints (P2), and compare the computational time of generating the initial population including 1000 agents by the homomorphous mapping (Koziel & Michalewicz, 1999) with that by the random method. The results are shown as in table 1.
Table 1. Comparison of computational times of generating the initial population including 1000 agents

The results in table 1 show the effectiveness of the use of the homomorphous mapping in generating the initial population.

Second, in order to investigate the efficiency of substeps 8-2 and 8-3, we compare the result of EMAS without 8-2, 8-3 with that of EMAS with 8-2, 8-3 by setting both the number of agents and the maximal generation number to 1000s. Results are shown as in table 2.

Table 2. The efficiency of substeps 8-2 and 8-3

The results in table 2 show that both substeps 8-2 and 8-3 are worth being introduced in the proposed method.

Next, in order to investigate the efficiency of substep 8-1 for improving the upper level objective function value, we apply EMAS without 8-1 and one with 8-1.

Table 3. The efficiency of substeps 8-1

To be more specific, problem A and B are formulated as:

Problem A: Upper level decision variables $x_1 = (x_1, x_2, x_3, x_4)$, lower level decision variables: $x_2 = (x_5, x_6, x_7, x_8)$.

- **minimize** $x_1$: $f_1(x_1, x_2) = x_1^3+(x_2-2)^2-x_3x_4-2x_5^2+x_6^4+(7-x_8)^2$
  where $x_2$ solves

- **minimize** $x_2$: $f_2(x_1, x_2) = -2x_1^2+x_1^3+2x_3^2-x_4^4+3x_5^3-2x_6+5x_7+4x_8^2$

- **subject to**: $4x_1^2-3x_2^3+5(x_3-4)^2-6x_4-x_5x_6-3x_7^4+5x_8 \leq 0$
  $2x_1x_7-x_2^2-3x_3-4x_4^2+x_5^2-x_6^3-2x_7^2 \leq -12$
  $5x_1+x_2-6x_3+4x_4-6x_5-x_6-3x_7+x_8 \leq 5$
  $-5 \leq x_j \leq 5, j = 1, \ldots, 8,$
Problem B: Upper level decision variables $x_1 = (x_1, \ldots, x_{10})$, lower level decision variables $x_2 = (x_{11}, \ldots, x_{20})$.

$$\text{minimize } f_1(x_1, x_2) = \min \left( \sum_{j=1}^{20} \cos^4(x_j) - 2 \prod_{j=1}^{20} \cos^2(x_j), \prod_{j=1}^{20} x_j \right)$$

where $x_2$ solves

$$\text{minimize } f_2(x_1, x_2) = (x_1-x_{14})(x_{17}-x_6)-(x_4-x_{11})(x_{18}-x_7)+(x_8-x_{12})(x_3-x_{19}) -(x_{13}-x_3)(x_{10}-x_6) +(x_20-x_9)(x_2-x_{15})$$

subject to

$$0.75 - \prod_{j=1}^{20} x_j \leq 0$$

$$\prod_{j=1}^{20} x_j - 7.5 \cdot 20 \leq 0$$

$$0 \leq x_j \leq 10, j = 1, \ldots, 20.$$

From the results in table 3, the procedure of substep 8-1 is meaningful for enhancing the efficiency of the proposed method. Furthermore, in order to investigate the efficiency of the proposed EMAS, we compare the result obtained by it with that by two-level PSO method (Niwa et al., 2006) in the application of both methods to a two-level nonlinear programming problem with 10 decision variables and 3 constraints. In the numerical experiment, the number of agents is 1000, the maximal generation number is 1000 and the number of trials is 10. Table 4 shows the best value, the average value, the worst value of the upper level objective function obtained by the proposed EMAS in 10 trials, the best value obtained by the two-level PSO (Niwa et al., 2006) and the average computational time.

7. Conclusion

In this chapter, we discussed an efficient approximate solution method based on evolutionary multi-agent systems to obtain Stackelberg solutions to noncooperative two-level programming problems. In particular, we proposed a new EMAS by incorporating the concept of homomorphous mapping to generate feasible initial agents, the theory of the Kuhn-Tucker condition for checking whether an agent exists around IR or not, and the idea of reproduction in the infeasible region, together with the introduction of the searching process of the infeasible region by infeasible agents in order to widen the search area. Furthermore, we showed the efficiency of the proposed EMAS by comparing it with an existing method, the two-level PSO method, through some numerical experiments. From the numerical experimental results, it is indicated that the proposed EMAS is superior to the two-level PSO method, and that the proposed EMAS is promising as an optimization method for two-level nonlinear programming problems. In the near future, we will extend the proposed method to noncooperative and cooperative multi-level programming.

8. References

A multi-agent system (MAS) is a system composed of multiple interacting intelligent agents. Multi-agent systems can be used to solve problems which are difficult or impossible for an individual agent or monolithic system to solve. Agent systems are open and extensible systems that allow for the deployment of autonomous and proactive software components. Multi-agent systems have been brought up and used in several application domains.
