Abstract

We provide machine-independent characterizations of some complexity classes, over an arbitrary structure, in the model of computation proposed by L. Blum, M. Shub and S. Smale. We show that the levels of the polynomial hierarchy correspond to safe recursion with predicative minimization and the levels of the digital polynomial hierarchy to safe recursion with digital predicative minimization. Also, we show that polynomial alternating time corresponds to

safe recursion with predicative substitutions and that digital polynomial alternating time corresponds to safe recursion with digital predicative substitutions.

1 Introduction

In the last decades complexity theory developed in many directions to offer a broad perspective of the complexity of computations. Two directions which are relevant for this paper are the extension of complexity theory to domains other than the set \{0, 1\} and the characterization of complexity classes in machine-independent terms.

A seminal paper for the first direction above is the one by Blum, Shub, and Smale [?] where a theory of computation and complexity over the real numbers was developed with the aim of capturing the features of numeric computations such as those done in numerical analysis. The setting of [?] actually considers computations over arbitrary rings \( R \), the case \( R = \mathbb{R} \) being their major case of interest and the case \( R = \mathbb{Z}/2 \) being the classical one. A further extension is carried out in [?] where computations over arbitrary structures are pursued.

Concerning the second direction above, a seminal result is the characterization by Fagin [?] of non-deterministic polynomial time relying on finite model theory. This result can be said to be implicit in the sense that it characterizes complexity classes in machine-independent terms. Other works followed along these lines [?, ?, ?, ?, ?]. Another approach giving implicit characterizations of complexity classes was initiated by Bellantoni and Cook [?] who characterized the class of functions computable in polynomial time as the smallest class of functions containing some basic functions and closed under some operations. This result is a subrecursive version of the classical result by Kleene characterizing Turing computable functions as those being recursive and is based on a purely syntactic distinction between different types of arguments (which avoids explicit upper bounds on computational resources). Further results characterizing function algebras in complexity classes appear in [?, ?].

A natural research line is to combine the two directions above by looking for implicit characterization of complexity classes over the reals (or, more generally, over arbitrary structures). A first step towards this goal was given in [?] where the basis for an extension of Fagin’s result to arbitrary structures was set, and in [?, ?] where several complexity classes over \( \mathbb{R} \) were characterized in this way. Then, in [?], we exhibited machine-independent characterizations of the classes of functions over an arbitrary structure computable in polynomial sequential or parallel time. This extended the classical characterizations in [?] and [?].

The goal of this paper is to further characterize other classes of computable functions over an arbitrary structure. We will do so for classes of function computable in polynomial time by machines making use of diverse forms of alternation.

Over an arbitrary structure, two kinds of nondeterminism may be considered according to whether the witness is allowed to be an arbitrary element of the struc-
ture or is restricted to be in \{0,1\}. The latter is usually called *digital* and a letter D is used to denote complexity classes arising from the use of digital nondeterminism. Note that in classical complexity theory, i.e., over a finite structure, these two notions of nondeterminism coincide and they yield the same polynomial hierarchy and class of polynomial alternating time. Moreover, polynomial alternating time coincides with PSPACE and with PAR (the class of sets decided in parallel polynomial time). This need not to be so over infinite structures. For instance, over \((\mathbb{R}, +, -, *, /, \leq)\), we have the following inclusions of complexity classes [1]

\[
\begin{array}{ccc}
\text{DPAT}_\mathbb{R} & \nearrow & \text{PAT}_\mathbb{R} \\
\searrow & \nearrow & \text{PAR}_\mathbb{R} \\
\text{PH}_\mathbb{R} & \nearrow & \text{EXP}_\mathbb{R} \\
\searrow & & \text{PEXP}_\mathbb{R}
\end{array}
\]

where an arrow means inclusion, \text{EXP}_\mathbb{R} denotes exponential time, \text{PEXP}_\mathbb{R} parallel exponential time, \text{PH}_\mathbb{R} is the polynomial hierarchy, and \text{PAT}_\mathbb{R} polynomial alternating time. In addition the two inclusions \text{PAR}_\mathbb{R} \subset \text{PAT}_\mathbb{R} and \text{PAR}_\mathbb{R} \subset \text{EXP}_\mathbb{R} are known to be strict.

When restricted to classical complexity, our characterizations of \text{PAT} and \text{DPAT}, combined with our previous one of \text{PAR} in [1], provide several new original alternative characterizations of \text{PSPACE}.

Furthermore, the minimization schemes we introduce for coping with nondeterminism, related to Hilbert choice operator and to the operators used to tailor recursion [2, ?], may shed some light on the nature of choice operators.

Our results provide a background for designing methods deriving computational properties from programs along the lines of [2, ?, ?] in classical complexity.

The rest of this paper is structured as follows.

In Sections 2 and 3 we define basic notions and recall the characterizations of deterministic complexity classes from [2]. Then, in Section 4, we provide a characterization of the polynomial hierarchy. Minor changes allow us to characterize the digital polynomial hierarchy in Section 5. Section 6 is devoted to a characterization of polynomial alternating time, with a similar result for digital polynomial alternating time in Section 7. In Section 8, we use another approach, related to parallelism, to characterize differently the digital polynomial alternating time class. Section 9 contains a technical result showing the equivalence between simple safe recursion and simultaneous safe recursion.

2 Arbitrary Structures

**Definition 1** A *structure* \( \mathcal{K} = (\mathbb{K}, \{op_i\}_{i \in I}, rel_1, \ldots, rel_l, 0, 1) \) is given by some underlying set \( \mathbb{K} \), a family of operators \( op_i \), and a finite number of relations \( rel_1, \ldots, rel_l \). Constants correspond to operators of arity 0. While the index set
I may be infinite, the number of operators of arity greater than zero needs to be finite. We will not distinguish between operator and relation symbols and their corresponding interpretations as functions and relations respectively over the underlying set $\mathbb{K}$. We assume that the equality relation $=$ is a relation of the structure, and that there are at least two constant symbols, with different interpretations (denoted by $0$ and $1$ in the sequel) in the structure.

An example of structure is $\mathcal{K} = (\mathbb{R}, +, -, \cdot, =, \leq, \{c_r\}_{r \in \mathbb{R}})$. The theory of complexity over the reals developed in [?] corresponds to computations over this structure. Another example, corresponding to classical complexity and computability theory, is $\mathcal{K} = (\{0, 1\}, =, 0, 1)$.

We denote by $\mathbb{K}^* = \bigcup_{i \in \mathbb{N}} \mathbb{K}^i$ the set of words over the alphabet $\mathbb{K}$. The space $\mathbb{K}^*$ is the analogue to $\Sigma^*$ the set of all finite sequences of zeros and ones. Words of elements in $\mathbb{K}$ will be represented with overlined letters, while elements in $\mathbb{K}$ will be represented by letters: $\overline{a}$ stands for the word in $\mathbb{K}^*$ whose first letter is $a$ and which ends with the word $\overline{x}$. We denote by $\epsilon$ the empty word. The length of a word $\overline{w} \in \mathbb{K}^*$ is denoted by $|\overline{w}|$.

Roughly speaking, a BSS machine over $\mathcal{K}$ is a kind of Turing machine which is able to perform the basic operations $op_i$ and the basic tests $rel_1, \ldots, rel_l$ at unit cost, and whose tape cells can hold arbitrary elements of the underlying set $\mathbb{K}$. Operations $op_i$ of arity 0, i.e., constants, occur in a finite number in every machine. [?, ?]. We assume the reader familiar with the notion of BSS machine. Detailed accounts can be found in [?] —for structures like real and complex numbers— or [?] —for considerations about more general structures.

In this setting of machines over $\mathcal{K}$ resources such as time, parallel time or alternating time can be considered allowing one to define several complexity classes. In addition, complete problems for many of these classes can be exhibited. In a previous paper [?], we provided machine independent characterizations of the class functions computable in polynomial time. Since our work here relies on this characterizations we next briefly recall it.

### 3 Safe Recursive Functions

We shall define formally the set of safe recursive functions over an arbitrary structure $\mathcal{K}$, extending the notion of safe recursive functions over the natural numbers found in [?]. Safe recursive functions are defined in a similar manner as primitive recursive functions, i.e. as the closure of some basic functions under the application of some operations, among which one operation of safe recursion. However, in the spirit of [?], safe recursive functions have two different types of arguments, each of them having different properties and purposes. The first type of argument, called normal, can be used to make basic computation steps or to control recursion. The second type of argument, called safe, can not be used to control recursion. This
distinction between safe and normal arguments ensures that safe recursive functions
can be computed in polynomial time. Algebras of functions with this distinction be-
tween safe and normal arguments are sometimes denoted as BC-algebras, referring
to Bellantoni and Cook [?].

To emphasize the distinction between normal and safe variables we will write
\( f : N \times S \rightarrow R \) where \( N \) indicates the domain of the normal arguments, \( S \) that of the
safe arguments, and \( R \) the codomain of \( f \). If all the arguments of \( f \) are of one kind,
say safe, we will write \( \emptyset \) in the place of \( N \). Also, if \( \overline{x} \) and \( \overline{y} \) are these arguments, we
will write \( f(\overline{x}; \overline{y}) \) separating them by a semicolon “;”. Normal arguments are placed
at the left of the semicolon and safe arguments at its right.

**Definition 2** We call basic functions the following four kinds of functions:

(i) functions making elementary manipulations of words over \( K \).
For any \( a \in K, \overline{x}, \overline{x_1}, \overline{x_2} \in K^* \)
\[
\begin{align*}
\text{hd}(; a.\overline{x}) &= a \\
\text{tl}(; a.\overline{x}) &= \overline{x} \\
\text{cons}(; a.\overline{x_1}, \overline{x_2}) &= a.\overline{x_2}
\end{align*}
\]

(ii) projections. For any \( n \in \mathbb{N}, i \leq n, \)
\[
\text{Pr}_i^n(; \overline{x_1}, \ldots, \overline{x_i}, \ldots, \overline{x_n}) = \overline{x_i}.
\]

(iii) functions of structure. For any operator (including the constants treated as
operators of arity 0) \( op_i \) or relation \( rel_i \) of arity \( n_i \) we have the following initial
functions:
\[
\begin{align*}
\text{Op}_i(; a_1.\overline{x_1}, \ldots, a_{n_i}.\overline{x_{n_i}}) &= (op_i(a_1, \ldots, a_{n_i})).\overline{x_{n_i}} \\
\text{Rel}_i(; a_1.\overline{x_1}, \ldots, a_{n_i}.\overline{x_{n_i}}) &= \begin{cases} 
1 & \text{if } rel_i(a_1, \ldots, a_{n_i}) \\
0 & \text{otherwise.}
\end{cases}
\end{align*}
\]
The equality relation will be denoted Equal.

(iv) a selector function
\[
\text{Select}(; \overline{x}, \overline{y}, \overline{z}) = \begin{cases} 
\overline{y} & \text{if } \text{hd}(\overline{x}) = 1 \\
\overline{z} & \text{otherwise.}
\end{cases}
\]

**Definition 3** The set of safe recursive functions over \( \mathcal{K} \), denoted by \( \text{SR}_{\mathcal{K}} \), is the
smallest set of functions \( f : (K^*)^p \times (K^*)^q \rightarrow K^* \) containing the basic safe functions,
and closed under the following operations:
1. Safe composition. Let \( g : (\mathbb{K}^*)^m \times (\mathbb{K}^*)^n \to \mathbb{K}^* \), \( h_1, \ldots, h_m : \mathbb{K}^* \times \emptyset \to \mathbb{K}^* \) and \( h_{m+1}, \ldots, h_{m+n} : \mathbb{K}^* \times \mathbb{K}^* \to \mathbb{K}^* \) be safe recursive functions. Their safe composition is the function \( f : \mathbb{K}^* \times \mathbb{K}^* \to \mathbb{K}^* \) defined by
\[
 f(x; y) = g(h_1(x), \ldots, h_m(x); h_{m+1}(x; y), \ldots, h_{m+n}(x; y)).
\]

2. Safe recursion. Let \( h : \mathbb{K}^* \times \mathbb{K}^* \to \mathbb{K}^* \) and \( g : (\mathbb{K}^*)^2 \times (\mathbb{K}^*)^2 \to \mathbb{K}^* \). We define \( f : (\mathbb{K}^*)^2 \times \mathbb{K}^* \to \mathbb{K}^* \) by safe recursion as follows
\[
 f(\epsilon, x; y) = h(x; y) \quad f(a.z, x; y) = g(z, x; f(z, x; y)).
\]

**Theorem 1 ([?])** Over any structure \( \mathcal{K} = (\mathbb{K}, \{op_i\}_{i \in I}, rel_1, \ldots, rel_l, 0, 1) \), a function is computed in polynomial time by a BSS machine if and only if it can be defined as a safe recursive function over \( \mathcal{K} \).

Let \( \Phi \) be a set and \( F \) a complexity class of functions (resp. of sets). We denote by \( F^\Phi \) the class of functions computable (resp. sets decidable) by a machine in \( F \) with oracle \( \Phi \). When \( G \) is another complexity class, \( F^G \) denotes the class \[ \bigcup_{\Phi \in G} F^\Phi. \]

**Definition 4** Given a function \( \phi : \emptyset \times \mathbb{K}^* \to \mathbb{K}^* \), the set of safe recursive functions relative to \( \phi \) over \( \mathcal{K} \), denoted by \( SR_{\mathcal{K}}(\phi) \), is the smallest set of functions \( f : (\mathbb{K}^*)^p \times (\mathbb{K}^*)^q \to \mathbb{K}^* \) containing the basic safe functions and \( \phi \), and closed under safe composition and safe recursion.

The following result is a relativization of our previous Theorem 1.

**Theorem 2** Let \( \Phi \in \mathbb{K}^* \) be a decision problem over \( \mathcal{K} \), and denote by \( \phi : \emptyset \times \mathbb{K}^* \to \{0, 1\} \) its characteristic function. Then, a function is in the class \( FP^\Phi_{\mathcal{K}} \) of functions computable in polynomial time with oracle \( \Phi \) if and only if it can be defined in \( SR_{\mathcal{K}}(\phi) \).

**Proof.** The proof is based upon that of Theorem 1 as it appears in [?]. The idea is to write a safe recursive function computing the output of a deterministic polynomial time BSS machine over \( \mathcal{K} \). One just needs to add one case in the enumeration of all types of nodes of the machine: An oracle node \( q \in \mathbb{N} \) calling for an oracle function \( \phi \) has associated functions
\[
 G_i(\overline{x}_1, \overline{x}_2) = \alpha q' \\
 H_i(\overline{x}_1, \overline{x}_2) = \overline{x}_1 \\
 I_i(\overline{x}_1, \overline{x}_2) = \phi(\overline{x}_2). 
\]
Here, we recall from [?], \( \alpha = 0 \) and the word \( \alpha^q' \) denotes the next node \( q' \) of \( q \). The rest of the proof carries on without modification. Note that in [?] we were dealing with simultaneous safe recursion. To be fully formal we need to prove that simple safe recursion is enough. We do so in Proposition 1 in Section 9. \( \square \)

We shall next introduce a technical lemma needed later in our proofs.

**Lemma 1** Assume \( f : (\mathbb{K}^*)^2 \times \emptyset \rightarrow \mathbb{K}^* \) is in \( \text{SR}_{\mathbb{K}}(\phi) \). Moreover, assume that there exists a polynomial \( p \) such that, for all \( \overline{x}, \overline{y} \in \mathbb{K}^* \), \( f(\overline{x}, \overline{y};) \) can be evaluated in time bounded by \( p(|\overline{x}|) \). Then, there exists \( f' : \mathbb{K}^* \times \mathbb{K}^* \rightarrow \mathbb{K}^* \in \text{SR}_{\mathbb{K}}(\phi) \) such that

\[
f'(\overline{x}; \overline{y}) = f(\overline{x}, \overline{y};).
\]

**Proof.** The idea is once again to follow the proof of Theorem 1. A BSS machine, on input \( \overline{z} \), can be simulated by a safe recursive function \( \text{Eval} \) such that \( \text{Eval}(0^t; \overline{z}) \) gives the content of the tape after \( t \) computation steps. Its normal argument \( 0^t \) can be seen as a clock for the BSS machine. Assume \( M \) is a BSS-machine computing \( f(\overline{x}, \overline{y};) \) in time \( p(\overline{x}) \). Theorem 1 gives a safe recursive function \( f_p : \mathbb{K}^* \times \emptyset \rightarrow \mathbb{K}^* \) such that \( f_p(\overline{x};) = 0^p(\overline{x}) \). Consider a safe recursive function \( \text{Cons} \) such that \( \text{Cons}(\overline{x}; \overline{y}) = \overline{x}. \overline{y} \). Then, \( f'(\overline{x}; \overline{y}) = \text{Eval}(f_p(\overline{x}); \text{Cons}(\overline{x}; \overline{y})) \). \( \square \)

## 4 A Characterization of \( \text{PH}_{\mathbb{K}} \)

### 4.1 Polynomial Hierarchy over a Structure \( \mathbb{K} \)

As in the classical setting, the polynomial hierarchy over a given structure \( \mathbb{K} \) can be defined in several equivalent ways, including syntactic descriptions, or semantic definitions by successive relativizations of non-deterministic polynomial time (see [?]).

Recall some basic complexity classes:

- \( \text{P}_{\mathbb{K}} \) is the class of problems over \( \mathbb{K} \) decided in polynomial time. We denote by \( \text{FP}_{\mathbb{K}} \) the class of functions over \( \mathbb{K} \) computed in polynomial time.
- A decision problem \( A \) is in \( \text{NP}_{\mathbb{K}} \) if and only if there exists a decision problem \( B \) in \( \text{P}_{\mathbb{K}} \) and a polynomial \( p_B \) such that \( \overline{x} \in A \) if and only if there exists \( \overline{y} \in \mathbb{K}^* \) with \(|\overline{y}| \leq p_B(|\overline{x}|) \) satisfying \( (\overline{x}, \overline{y}) \in B \).
- A decision problem \( A \) is in \( \text{coNP}_{\mathbb{K}} \) if and only if there exists a decision problem \( B \) in \( \text{P}_{\mathbb{K}} \) and a polynomial \( p_B \) such that \( \overline{x} \in A \) if and only if for all \( \overline{y} \in \mathbb{K}^* \) with \(|\overline{y}| \leq p_B(|\overline{x}|) \), \( (\overline{x}, \overline{y}) \) is in \( B \).

**Definition 5** Let \( \Sigma^0_{\mathbb{K}} = \text{P}_{\mathbb{K}} \) and, for \( i \geq 1 \), \( \Sigma^i_{\mathbb{K}} = \text{NP}^i_{\mathbb{K}} \), \( \Pi^i_{\mathbb{K}} = \text{coNP}^i_{\mathbb{K}} \).

The polynomial time hierarchy over \( \mathbb{K} \) is \( \text{PH}_{\mathbb{K}} = \bigcup_{i=0}^{\infty} \Sigma^i_{\mathbb{K}} = \bigcup_{i=0}^{\infty} \Pi^i_{\mathbb{K}} \).
A function is in $F\Delta^i_K$ if it computable in polynomial time by a machine over $K$ which queries an oracle in $\Sigma^i_K$. That is, $F\Delta^i_K = FP^{\Sigma^i_K}_K = FP^{\Pi^i_K}_K$.

The functional polynomial time hierarchy over $K$ is $FPH_K = \bigcup_{i=0}^{\infty} F\Delta^i_K$.

Remark 1 Extending the classical notion of polynomial time reduction between decision problems, complete problems for every of the $\Sigma^i_K$ and $\Pi^i_K$ have been shown to exist [?, ?].

4.2 Safe Recursion with Predicative Minimization

In the spirit of [?], we now introduce the notion of predicative minimization.

**Definition 6** Given $h : K^* \times (K^*)^2 \to K^*$, we define $f : K^* \times K^* \to K$ by predicative minimization as follows

$$f(x; a) = \exists b(h(x; a, b)) = \begin{cases} 1 & \text{if there exists } b \in K^* \text{ such that } h(x; a, b) = 0 \\ 0 & \text{otherwise.} \end{cases}$$

We now introduce new sets of functions.

**Definition 7** Let $F$ be a class of BC functions. The set of restricted safe recursive functions relative to $F$ over $K$, denoted by $\text{RSR}_K(F)$, is the smallest set of functions containing the basic safe functions and $F$, and closed under the following restricted safe composition scheme

$$f(x; y) = g(h_1(x;), \ldots, h_m(x;); h_{m+1}(x; y), \ldots, h_{m+n}(x; y)).$$

where the $h_i$ belong to $\text{RSR}_K(F)$ and $g$ to $\text{SR}_K$, and the following restricted safe recursion scheme

$$f(\epsilon, x; y) = h(x; y)$$
$$f(a, z, x; y) = g(z, x; f(z, x; y), y)$$

where $h$ belongs to $\text{RSR}_K(F)$ and $g$ to $\text{SR}_K$. This implies that no function in $F \setminus \text{SR}_K$ may be involved in the definition of $g$.

**Definition 8** Assume $F$ is a class of functions: a function $f$ is in $\varphi F$ if it is defined with one predicative minimization over a function $h$ of $F$.

We define by induction the following sets:

- $F^0_K = \text{SR}_K$.
- $F^{i+1}_K = \text{RSR}_K(F^i_K \cup \varphi F^i_K)$, for $i \geq 0$.

We denote by $\varphi PH_K = \bigcup_{i \in \mathbb{N}} F^i_K$ the closure of the basic safe functions over $K$ under the application of restricted safe recursion, predicative minimization and safe composition.
**Lemma 2**  This notion of restricted safe recursion ensures that, for any function $f$ in $F^i_{K}$, there are at most $i$ nested predicative minimizations. This bound does not depend on the arguments of $f$. In other words, there exists $h$ in SR$_K$ and $f_1, \ldots, f_n$ in $F_{K}^{i-1}$, such that, for all $x = (x_1, \ldots, x_l)$,

$$f(x; \bar{y}) = h(x; \emptyset x_1(f_1(x; \bar{y})), \ldots, \emptyset x_n(f_n(x; \bar{y}))).$$

We denote this as a normal form for $f$.

**Proof.** By induction on $i$ and on the definition of $f$:

- If $i = 0$, this normal form holds.
- If $f$ is a basic safe function, this normal form holds as well.
- If $f$ is defined with restricted safe composition as in Definition 7, $g$ belongs to SR$_K$, and we may apply the induction hypothesis on the $h_i$.
- If $f$ is defined with restricted safe recursion as in Definition 7 define:

$$f'(c, \bar{x}; \bar{y}, \bar{t}) = \bar{t}$$

$$f'(a, \bar{x}, \bar{y}, \bar{t}) = g(\bar{x}, \bar{y}, f'(\bar{x}, \bar{y}, \bar{t}), \bar{y})$$

$f'$ belongs to SR$_K$, $f'(\bar{x}, \bar{y}, h(\bar{x}, \bar{y})) = f(\bar{x}, \bar{y})$, and we may apply the induction hypothesis on $h$.
- If $f$ is defined with predicative minimization $f(\bar{x}; a) = \emptyset b(h(\bar{x}; a, b))$, by definition of $F^i_K$ $h$ belongs to $F^{i-1}_K$ and this is also a normal form.

$\square$

**Lemma 3**  Assume $f : (\mathbb{K}^*)^n \times \emptyset \to \mathbb{K}^*$ is a function in $F\Delta^i_K$. Then $f$ can be defined in $F^i_K$.

**Proof.** By induction on $i$. For $i = 0$, $f$ is in $F\Delta^0_K = FP_K$ and we may apply Theorem 1. Assume now that the result holds for $i > 0$.

Let $f$ be a function in $F\Delta^i_K$. By definition of $F\Delta^i_K$, there exist a polynomial time BSS machine $M_f$ and a set $\Phi$ in $\Sigma^i_K$ such that, for all $\bar{x} \in \mathbb{K}^*$, $f(\bar{x})$ is computed by $M_f$ with oracle $\Phi$. We are now establishing that the oracle $\Phi$ can be denoted by a function in $F^i_K$.

Since $\Phi \in \Sigma^i_K = NP_{K}^{\Sigma^{i-1}_K}$ there exist a deterministic polynomial-time BSS machine $M_g$ over $K$, a polynomial $p$ and a set $\Psi \in \Sigma^{i-1}_K$ such that

$$\bar{x} \in \Phi \iff \exists \bar{y} \text{ s.t. } M_g \text{ accepts } (\bar{x}, \bar{y}) \text{ with oracle } \Psi \text{ and } |\bar{y}| < p(|\bar{x}|).$$

Denote by $g$ the characteristic function computed by $M_g$ with oracle $\Psi$ and let $\psi$ be the characteristic function of $\Psi$. Then, apply Theorem 2: $g$ belongs to SR$(\psi)_K$. 

9
Since the evaluation time of \( M_\delta \) on \((\overline{\pi}, \overline{\gamma})\) is polynomial in \(|\overline{\pi}|\), Lemma 1 gives \( g' \) in \( \text{SR}(\psi)_K \) such that: \( g'(\overline{\pi}, \overline{\gamma}) = g(\overline{\pi}, \overline{\gamma}) \). Therefore \( \phi(\overline{\pi}; \overline{\gamma}) = \mathcal{E}(g'(\overline{\pi}; \overline{\gamma})) \). By induction hypothesis, the functions \( f, f_1, \ldots, f_n \) belong to \( \text{FP}^{\Delta_{K}^{-1}}_i \). Then, we deduce that \( \phi \) belongs to \( \text{F}^i_K \) and therefore so does \( f \).

\[ \square \]

**Lemma 4** Assume \( f: (\mathbb{K}^*)^n \times \emptyset \to \mathbb{K}^* \) is a function in \( \text{F}^i_K \). Then it belongs to \( \text{F}^{\Delta_{K}^{-1}}_i \).

**PROOF.** By induction on \( i \). For \( i = 0 \), the result is a straightforward consequence of Theorem 1. Assume now that the result holds for \( i > 0 \).

Assume \( f \) is a function in \( \text{F}^i_K \). Then, as in Lemma 2,

\[ f(x; \cdot) = h(x; \mathcal{E}(f_1(x; \overline{\pi})), \ldots, \mathcal{E}(f_n(x; \overline{\pi}))) \]

By induction hypothesis, the functions \( f_1, \ldots, f_n \) belong to \( \text{FP}^{\Delta_{K}^{-1}}_i \). The corresponding decision problems \( f_1(x; \overline{\pi}) = 0, \ldots, f_n(x; \overline{\pi}) = 0 \) belong to \( \text{P}^{\Delta_{K}^{-1}}_i = \Sigma_{K}^{-1} \). Indeed, they use a polynomial number of queries in \( \Sigma_{K}^{-1} \). If \( S_{i-1} \) denotes a complete problem in \( \Sigma_{K}^{-1} \) (see Remark 1), we can replace these different oracles by \( S_{i-1} \) (by making the oracle machine compute the reductions).

Define \( g_j(x; \cdot) = \mathcal{E}(f_j(x; \overline{\gamma})) \) for \( 1 \leq j \leq n \). Then, \( g_j \) is the characteristic function of a set in \( \Sigma_{K}^i \). Indeed, if there exists \( \overline{\gamma}_j \in \mathbb{K}^* \) such that \( f_j(x; \overline{\gamma}) = 0 \), since the evaluation time for \( f_j(x; \overline{\gamma}) \) is bounded by \( p_j(|x|) \) for some polynomial \( p_j \), only the first \( p_j(|x|) \) elements of \( \overline{\gamma}_j \) may possibly be taken into account. Therefore, there exists \( \overline{\gamma}_j \in \mathbb{K}^* \) of length \( p_j(|x|) \) such that \( f_j(x; \overline{\gamma}_j) = 0 \), which proves the claim. Therefore, \( f \) can be computed in polynomial time using \( n \) oracles in \( \Sigma_{K}^i \). If \( S_i \) denotes a complete problem in \( \Sigma_{K}^i \), again, we can replace these \( n \) different oracles by \( S_i \): \( f \in \text{FP}^{\Sigma_{K}^i}_i = \text{F}^{\Delta_{K}^{-1}}_i \).

\[ \square \]

Lemmas 3 and 4 yield our first main characterization.

**Theorem 3** A function: \((\mathbb{K}^*)^n \times \emptyset \to \mathbb{K}^* \) belongs to \( \text{F}^{\Delta_{K}^{-1}}_i \) if and only if it is defined in \( \text{F}^i_K \).

**Example 1** Over the real numbers, an example of \( \text{NP}_\mathbb{R} \)-complete problem is 4FEAS: does a given polynomial of degree four have a zero? Assume by Theorem 1 that the safe recursive function \( p(\overline{x}; \overline{\gamma}) \) evaluates a polynomial encoded by \( \overline{x} \) on an input \( \overline{\gamma} \). Then 4FEAS is decided on \( \overline{x} \) by \( f(\overline{x}) = \mathcal{E}(p(\overline{x}; \overline{\gamma})) \).

**Corollary 1** A decision problem over \( \mathcal{K} \) belongs to \( \text{PH}_\mathcal{K} \) if and only if its characteristic function is defined in \( \mathcal{E}\text{PH}_\mathcal{K} \).
5 A Characterization of DPH\(\mathcal{K}\)

5.1 Digital Polynomial Hierarchy over a Structure \(\mathcal{K}\)

**Definition 9** A set \(S \subseteq \mathbb{K}^*\) belongs to DNP\(\mathcal{K}\) if and only if there exist a polynomial \(p\) and a polynomial time BSS machine \(M\) over \(\mathcal{K}\) such that, for all \(x \in \mathbb{K}^*\),

\[
\pi \in S \iff \exists y \in \{0, 1\}^* \text{ s.t. } |y| \leq p(|x|) \text{ and } M \text{ accepts } (x, y).
\]

Let DΣ\(\mathcal{K}\)\(_0\) = P\(\mathcal{K}\) and, for \(i \geq 1\), DΣ\(\mathcal{K}\)\(_i\) = DNP\(\mathcal{K}\)\(\text{DΣ}^{i-1}{\mathcal{K}}\), DΠ\(\mathcal{K}\)\(_i\) = coDNP\(\mathcal{K}\)\(\text{DΣ}^{i-1}{\mathcal{K}}\).

The digital polynomial time hierarchy is DPH\(\mathcal{K}\) = \(\bigcup_{i=0}^{\infty} \text{DΣ}^i{\mathcal{K}}\) = \(\bigcup_{i=0}^{\infty} \text{DΠ}^i{\mathcal{K}}\).

A function is in DF∆\(\mathcal{K}\)\(_i\) if it computable in polynomial time by a machine over \(\mathcal{K}\) which queries an oracle in DΣ\(\mathcal{K}\)\(_i\). That is, DF∆\(\mathcal{K}\)\(_i\) = FP\(\text{DΣ}^i{\mathcal{K}}\) = FP\(\text{DΠ}^i{\mathcal{K}}\).

The functional digital polynomial time hierarchy is DFPH\(\mathcal{K}\) = \(\bigcup_{i=0}^{\infty} \text{DF∆}^i{\mathcal{K}}\).

In this digital version of the polynomial hierarchy, witnesses for a given problem are discrete choices among given values, and not arbitrary elements of the structure. As in the previous section, complete problems have been shown to exist for every level of this hierarchy.

5.2 Safe Recursion with Digital Predicative Minimization

Similarly to the notion of predicative minimization of the previous section, we introduce the notion of digital predicative minimization.

**Definition 10** Given \(h : \mathbb{K}^* \times (\mathbb{K}^*)^2 \rightarrow \mathbb{K}^*\), we define \(f : \mathbb{K}^* \times \mathbb{K}^* \rightarrow \mathbb{K}^*\) by digital predicative minimization as follows

\[
f(\pi; a) = \exists b \in \{0, 1\}^* \text{ s.t. } h(\pi; a, b) = 0
\]

**Definition 11** Let \(F\) be a class of functions. A function \(f\) is in \(\mathcal{E}_0 F\) if it is defined with one predicative minimization over a function \(h\) of \(F\).

We define by induction the following sets:

- \(dF^0{\mathcal{K}} = \text{SR}\mathcal{K}\)
- \(dF^{i+1}{\mathcal{K}} = \text{RSR}\mathcal{K}(dF_i{\mathcal{K}} \cup \mathcal{E}_0 F_i{\mathcal{K}})\), for \(i \geq 0\).

We denote by \(\mathcal{E}_0 PH\mathcal{K}\) the closure of the basic safe functions over \(\mathcal{K}\) under the application of projections, restricted safe recursion, digital predicative minimization and safe composition.

The proof of Theorem 3, *mutatis mutandis*, yields the following results.

**Theorem 4** A function: \((\mathbb{K}^*)^n \times \emptyset \rightarrow \mathbb{K}^*\) belongs to DFΔ\(\mathcal{K}\)\(_i\) if and only if it is defined in \(dF_i{\mathcal{K}}\).
Corollary 2 A decision problem over \( \mathcal{K} \) belongs to \( \text{DPH}_\mathcal{K} \) if and only if its characteristic function is defined in \( \mathfrak{D}_0 \text{DPH}_\mathcal{K} \).

Example 2 Over the real numbers, a problem in \( \text{D}\Sigma^1_\mathbb{R} \) is KNAPSACK: given \( n \) objects of weight \( w_i \in \mathbb{R} \) and value \( v_i \in \mathbb{R} \), a weight limit \( W \) and a minimal value \( V \), can we carry a total value at least \( V \) with total weight at most \( W \)? Assume by Theorem 1 that the safe recursive function \( v(\bar{x}; \bar{y}) \) decides whether, for an instance described by \( \bar{x} \) in size polynomial in \( n \), a choice among the objects described by \( \bar{y} \in \{0, 1\}^n \), the requirements of weight and value are satisfied. KNAPSACK is then decided on \( \bar{x} \) by \( f(\bar{x};) = \mathfrak{D}_0 \bar{y}(v(\bar{x};\bar{y})) \).

When considering finite structures, this naturally yields a characterization of the classical polynomial hierarchy alternative to the one found in [?].

Corollary 3 A decision problem belongs to \( \text{PH}_\mathcal{K} \) if and only if its characteristic function is defined in \( \mathfrak{D}_0 \text{DPH}_{\{0,1\}} \).

6 A Characterization of \( \text{PAT}_\mathcal{K} \)

Definition 12 A set \( S \subseteq \mathbb{K}^* \) belongs to \( \text{PAT}_\mathcal{K} \) (polynomial alternating time) if and only if there exist a polynomial function \( q : \mathbb{N} \rightarrow \mathbb{N} \) and a polynomial time BSS machine \( M_S \) over \( \mathcal{K} \) such that, for all \( \bar{x} \in \mathbb{K}^* \),

\[
\bar{x} \in S \iff \exists a_1 \in \mathbb{K} \forall b_1 \in \mathbb{K} \ldots \exists a_q(|\bar{x}|) \in \mathbb{K} \forall b_q(|\bar{x}|) \in \mathbb{K}
M_S \text{ accepts } (\bar{x}, a_1.b_1 \ldots a_q(|\bar{x}|).b_q(|\bar{x}|)).
\]

In addition, we define \( \text{FPAT}_\mathcal{K} = \text{FP}^{\text{PAT}_\mathcal{K}}_\mathcal{K} \).

When \( \mathcal{K} \) is the structure \( \{\{0, 1\}, =, 0, 1\} \), \( \text{PAT}_\mathcal{K} \) is PSPACE.

It is important to note that the number of quantifier alternations is not fixed, but depends on the length of the input and is polynomial in that length. It follows that \( \text{PH}_\mathcal{K} \subseteq \text{PAT}_\mathcal{K} \).

Definition 13 Given \( h : \mathbb{K}^* \times (\mathbb{K}^*)^2 \rightarrow \mathbb{K}^* \), we define \( f : \mathbb{K}^* \times \mathbb{K}^* \rightarrow \mathbb{K} \) by predicative substitution as follows

\[
f(\bar{x}; \bar{c}) = \mathfrak{D}^{[1]}c(h(\bar{x}; \bar{c}, c)) = \begin{cases} 
1 & \text{if there exists } c \in \mathbb{K} \text{ such that } h(\bar{x}; \bar{c}, c) = 0 \\
0 & \text{otherwise}.
\end{cases}
\]

Definition 14 Assume \( h : \mathbb{K}^* \times (\mathbb{K}^*)^2 \rightarrow \mathbb{K}^* \) and \( g : (\mathbb{K}^*)^2 \times (\mathbb{K}^*)^2 \rightarrow \mathbb{K}^* \) are given functions. The function \( f : (\mathbb{K}^*)^2 \times (\mathbb{K}^*)^2 \rightarrow \mathbb{K}^* \) is defined by safe recursion with predicative substitutions as follows

\[
f(\epsilon, \bar{x}; \bar{u}, \bar{y}) = h(\bar{x}; \bar{u}, \bar{y})
\]
\[
f(a.\bar{z}, \bar{x}; \bar{u}, \bar{y}) = g(\bar{z}, \bar{x}; \mathfrak{D}^{[1]}c(f(\bar{z}, \bar{c}, \bar{u}, \bar{y})), \bar{y}).
\]
Definition 15 The set $\mathfrak{E}^{[1]}\text{PAT}_K$ of safe recursive functions with predicative substitutions over $K$ is the closure of the basic safe functions under the application of safe composition, safe recursion and safe recursion with predicative substitutions.

Theorem 5 A function is computed in $\text{FPAT}_K$ if and only if it can be defined in $\mathfrak{E}^{[1]}\text{PAT}_K$.

Proof. Let $F$ be a function in $\text{FPAT}_K$, and denote by $G$ the associated oracle in $\text{PAT}_K$. There exists a polynomial time BSS machine $M$ over $K$, and a polynomial function $q : \mathbb{N} \to \mathbb{N}$ such that, for all $\bar{x} \in K^*$,

$$\bar{x} \in G \iff \exists a_1 \in K \exists b_1 \in K \ldots \exists a_{q(|\bar{x}|)} \in K \exists \neg b_{q(|\bar{x}|)} \in K$$

$M$ accepts $(\bar{x}, a_1 \cdot b_1 \ldots a_{q(|\bar{x}|)} \cdot b_{q(|\bar{x}|)})$.

Theorem 1 and Lemma 1 ensure that there exists a safe recursive function $f_M$ over $K$ such that, for any $(\bar{x}, \bar{y}) \in (K^*)^2$, $M$ accepts on input $(\bar{x}, \bar{y})$ if and only if $f_M(\bar{x}, \bar{y}) = 1$.

Consider now the function $F_G : (K^*)^2 \times K^* \to K^*$ deciding $G$. $F_G(\epsilon, \bar{x}; \bar{u})$ simulates $M$ on input $\bar{x}, \bar{u}$. The recurrence parameter $a.\bar{z}$ in $F_G(a.\bar{z}, \bar{x}; \bar{u})$ describes the shape of the quantifier sequence. $F_G$ is defined with quantified safe recursion as follows, where all tests can be easily done with composition and the Select function,

$$F_G(\epsilon, \bar{x}; \bar{u}) = f_M(\bar{x}, \bar{u})$$

$$F_G(a.\bar{z}, \bar{x}; \bar{u}) = \begin{cases} 
\mathfrak{E}^{[1]}c(F_G(\bar{x}, \bar{z}; c.\bar{u})) & \text{if } \text{hd}(; \bar{z}) = 1 \\
0 & \text{if } \text{hd}(; \bar{z}) = 0 \text{ and } \mathfrak{E}^{[1]}c(F_G(\bar{x}, \bar{z}; c.\bar{u})) = 1 \\
1 & \text{if } \text{hd}(; \bar{z}) = 0 \text{ and } \mathfrak{E}^{[1]}c(F_G(\bar{x}, \bar{z}; c.\bar{u})) = 0 \\
f_M(\bar{x}, \bar{u}) & \text{otherwise.}
\end{cases}$$

In addition, let $g_q : K^* \times \emptyset \to K^*$ such that $g_q(\bar{x};) = (1, 0)^{q(|\bar{x}|)}$. Since $g_q$ is computable in polynomial time over $K$, by Theorem 1, it is safe recursive. This function $g_q$ actually gives the type of the quantifier at every level of the quantifier alternation for any input $\bar{x}$ to the problem $G$.

It is easy to check by induction on $|\bar{x}|$ that $F_G(\text{cons}(1, g_q(\bar{x};);), \bar{x}; 0)$ decides whether $\bar{x}$ belongs to $G$. Therefore, the characteristic function $\chi_G$ of $G$ belongs to $\mathfrak{E}^{[1]}\text{PAT}_K$.

Consider a polynomial time machine $M'$ with oracle $G$ computing $F$. By Theorem 2, $F$ belongs to $\text{SR}_K(F_G)$, i.e., $F \in \mathfrak{E}^{[1]}\text{PAT}_K$.

The other direction of the proof is by induction on the definition of $f$. The only critical case is when $f$ is defined by safe recursion with predicative substitutions, as in Definition 14. In this case, $f(a.\bar{z}, \bar{x}; \bar{u}, \bar{y})$ equals 1 if and only if

$$(\exists c \in K f(\bar{x}, \bar{z}; c.\bar{u}, \bar{y}) = 0 \land g(\bar{z}, \bar{x}; 1, \bar{y}) = 1)$$

$$\lor \ (\forall c \in K f(\bar{x}, \bar{z}; c.\bar{u}, \bar{y}) \neq 0 \land g(\bar{z}, \bar{x}; 0, \bar{y}) = 1).$$
If \( g(\overline{z}, \overline{x}; 1, \overline{y}) = 1 \) and \( g(\overline{z}, \overline{x}; 0, \overline{y}) = 1 \), then \( f(\overline{a}, \overline{z}; \overline{u}, \overline{y}) = 1 \) and there is no need for a recursive call. If \( g(\overline{z}, \overline{x}; 1, \overline{y}) \neq 1 \) and \( g(\overline{z}, \overline{x}; 0, \overline{y}) \neq 1 \), then \( f(\overline{a}, \overline{z}; \overline{u}, \overline{y}) \neq 1 \) and there is no need for a recursive call either. If \( g(\overline{z}, \overline{x}; 1, \overline{y}) = 1 \) and \( g(\overline{z}, \overline{x}; 0, \overline{y}) \neq 1 \), then \( f(\overline{a}, \overline{z}; \overline{u}, \overline{y}) = 1 \) if and only if

\[
\exists c \in \mathbb{K} f(\overline{z}, \overline{x}; c, \overline{u}, \overline{y}) = 0.
\]

If \( g(\overline{z}, \overline{x}; 1, \overline{y}) \neq 1 \) and \( g(\overline{z}, \overline{x}; 0, \overline{y}) = 1 \), then \( f(\overline{a}, \overline{z}; \overline{u}, \overline{y}) = 1 \) if and only if

\[
\forall c \in \mathbb{K} f(\overline{z}, \overline{x}; c, \overline{u}, \overline{y}) \neq 0.
\]

Therefore, at every level of the recursion, the choice is determined by the function \( g \). By induction hypothesis, this can be done in \( \text{FPAT}_K \). When unfolding the recursion, we get a sequence of quantifiers \( Q_1, \ldots, Q_{|\overline{z}|+1} \) and a relation symbol \( r \in \{ =, \neq \} \) such that

\[
f(\overline{a}, \overline{z}; \overline{u}, \overline{y}) = 1 \text{ iff } Q_1 c_1 \in \mathbb{K}, \ldots, Q_{|\overline{z}|+1} c_{|\overline{z}|+1} \in \mathbb{K} h(\overline{z}, c_1, \ldots, c_{|\overline{z}|+1}, \overline{u}, \overline{y}) r 0.
\]

Apply the induction hypothesis on function \( h \). Then, \( f \) belongs to \( \text{FPAT}^{\text{FPAT}_K}_K \), with an oracle which computes \( g \) and gives the quantifier sequence. One just needs to note that \( \text{FPAT}^{\text{FPAT}_K}_K = \text{FPAT}_K \) to conclude.

\[\square\]

7 \hspace{1em} A Characterization of \( \text{DPAT}_K \)

The class \( \text{DPAT}_K \) is defined similarly to \( \text{PAT}_K \) but with all quantified variables belonging to \( \{0, 1\} \). Similarly, we can define \( \text{DFPAT}_K = \text{FPD}_K \).

Similarly to the notion of predicative substitution, we define the notion of digital predicative substitution.

**Definition 16** Given \( h : \mathbb{K}^* \times (\mathbb{K}^*)^2 \rightarrow \mathbb{K} \), we define \( f : \mathbb{K}^* \times \mathbb{K}^* \rightarrow \mathbb{K} \) by predicative substitution,

\[
f(\overline{x}; \overline{a}) = \mathcal{P}_0^{|\overline{x}|} c(h(\overline{x}; \overline{a}, c)) = \begin{cases} 1 & \text{if there exists } c \in \{0, 1\} \text{ such that } h(\overline{x}; \overline{a}, c) = 0 \\ 0 & \text{otherwise.} \end{cases}
\]

**Definition 17** Assume \( h : \mathbb{K}^* \times (\mathbb{K}^*)^2 \rightarrow \mathbb{K} \) and \( g : (\mathbb{K}^*)^2 \times (\mathbb{K}^*)^2 \rightarrow \mathbb{K}^* \) are given functions. The function \( f : (\mathbb{K}^*)^2 \times (\mathbb{K}^*)^2 \rightarrow \mathbb{K}^* \) is defined by safe recursion with digital predicative substitutions as follows

\[
\begin{align*}
f(\epsilon, \overline{x}; \overline{u}, \overline{y}) &= h(\overline{x}; \overline{u}, \overline{y}) \\
f(a, \overline{z}, \overline{x}; \overline{u}, \overline{y}) &= g(\overline{z}, \overline{x}; \mathcal{P}_0^{|\overline{z}|} cf(\overline{z}, \overline{x}; c, \overline{u}, \overline{y}), \overline{y})
\end{align*}
\]
Definition 18 The set $\mathcal{E}^{[1]} \text{DPAT}_K$ of safe recursive functions with digital predicative substitutions over $K$ is the closure of the basic safe functions under the application of safe composition, safe recursion and safe recursion with digital predicative substitutions.

Again, the proof of Theorem 5 yields, mutatis mutandis, the following result.

Theorem 6 A function is computed in $\text{DFPAT}_K$ if and only if it can be defined in $\mathcal{E}^{[1]} \text{DPAT}_K$.

When restricted to finite structures, this yields another characterization of PSPACE.

Corollary 4 A set $S \subseteq \{0, 1\}^*$ is in PSPACE if and only if its characteristic function can be defined in $\mathcal{E}^{[1]} \text{DPAT}_{\{0, 1\}}$.

8 An Alternative Characterization of $\text{DPAT}_K$

8.1 Safe Recursive Functions with Substitutions

In [?] we gave a characterization of the class of functions computable in parallel polynomial time in terms of a constructor called safe recursion with substitutions.

Definition 19 The set of functions defined with safe recursion with substitutions over $K$ is the smallest set of functions $f : (K^*)^p \times (K^*)^q \rightarrow K^*$, containing the basic safe functions, and closed under safe composition and the following Safe recursion with substitutions scheme.

Assume $h : K^* \times (K^*)^2 \rightarrow K^*$, $g : (K^*)^2 \times (K^*)^{l+1} \rightarrow K^*$, and $\sigma_j : \emptyset \times K^* \rightarrow K^*$ for $0 < j \leq l$ are given functions. The function $f : (K^*)^2 \times (K^*)^2 \rightarrow K^*$ is defined by safe recursion with substitutions as follows

$$f(\varepsilon, \varphi; \bar{u}, \bar{y}) = h(\varphi; \bar{u}, \bar{y})$$
$$f(a, \varphi; \bar{u}; \bar{y}) = g(\varphi, \varphi; f(\varphi, \varphi; \sigma_1(\bar{u}), \bar{y}), \ldots, f(\varphi, \varphi; \sigma_l(\bar{u}), \bar{y}), \bar{y}).$$

The functions $\sigma_j$ are called substitution functions.

Theorem 7 ([?]) Over any structure $K = (\mathbb{K}, \{op_i\}_{i \in I}, rel_1, \ldots, rel_l, 0, 1)$, a function is computed in parallel polynomial time by a (parallel) BSS machine if and only if it is defined as a safe recursive function with substitutions over $K$.

8.2 Safe Recursive Functions with Digital Substitutions

When restricted to finite structures, $\text{DPAT}_K$ coincides with $\text{PAR}_K$ and with PSPACE. However, when $K$ is arbitrary, we only have the inclusion $\text{DPAT}_K \subset$
PAR$_{\mathcal{K}}$. Based on our previous characterization of PAR$_{\mathcal{K}}$, some small restrictions on the type of the functions involved in the recursion scheme yield another characterization of DPAT$_{\mathcal{K}}$.

**Definition 20** We call *pseudo logical function* any function in the closure of operations of arity 0 (constants), projections and the selector function Select under the application of safe composition.

Since no recursion and no $tl$ function is involved in the definition of a pseudo logical function, its output depends only on the value of the first letter of its arguments, more precisely, on whether these are 1 or not since no relation is allowed either.

**Definition 21** Assume $h : \mathcal{K}^* \times \mathcal{K}^* \rightarrow \mathcal{K}^*$ is a given function, $g : (\mathcal{K}^*)^2 \times (\mathcal{K}^*)^2 \rightarrow \mathcal{K}^*$ is a pseudo logical function, and $\sigma_1, \sigma_2 : \emptyset \times \mathcal{K}^* \rightarrow \mathcal{K}^*$ are safe recursive functions. Function $f : \mathcal{K}^* \times \mathcal{K}^* \rightarrow \mathcal{K}^*$ can then be defined by *safe recursion with digital substitutions*:

\[
\begin{align*}
  f(\epsilon, \pi ; u) &= h(\pi ; u) \\
  f(a.\pi, \pi ; u) &= g(\pi, \pi ; f(\pi, \pi ; \sigma_1 ; u), f(\pi, \pi ; \sigma_2 ; u)).
\end{align*}
\]

We define the set of *safe recursive functions with digital substitutions* to be the closure of the basic safe functions under the application of safe composition, safe recursion and safe recursion with digital substitutions.

**Theorem 8** A function is in DFPAT$_{\mathcal{K}}$ if and only if it can be defined as a safe recursive functions with digital substitutions over $\mathcal{K}$.

**Proof.** Let $F$ be a function in DFPAT$_{\mathcal{K}}$, and denote by $G$ the associate oracle in DPAT$_{\mathcal{K}}$. There exists a polynomial time BSS machine $M$ over $\mathcal{K}$, and a polynomial function $q : \mathbb{N} \rightarrow \mathbb{N}$ such that, for any $\pi \in \mathcal{K}^*$, the following propositions are equivalent:

- (i): $\pi \in G$
- (ii): $\exists b_1 \in \{0, 1\}$ $\forall c_1 \in \{0, 1\}$ $\ldots$ $\exists b_{q(|\pi|)} \in \{0, 1\}$ $\forall c_{q(|\pi|)} \in \{0, 1\}$ $M$ accepts $(\pi, b_1 c_1 \ldots b_{q(|\pi|)} c_{q(|\pi|)}).

Theorem 1 ensures that there exists a safe recursive function $f_M$ over $\mathcal{K}$ such that, for any $(\pi, \gamma) \in (\mathcal{K}^*)^2$, $M$ accepts on input $(\pi, \gamma)$ if and only if $f_M(\pi, \gamma) = 1$. Moreover, define $g_q : \mathcal{K}^* \times \emptyset \rightarrow \mathcal{K}^*$ such that $g_q(\pi ; ) = (1.0)^{q(|\pi|)}$. The existence of such a $g_q$ is once again given by Theorem 1. This function $g_q$ actually gives the type of the quantifier at every level of the quantifier alternation for any input $\pi$ to the problem $G$.  

16
Define now the following function,

\[ F_G(\epsilon, \bar{x}; \bar{u}) = f_M(\bar{x}; \bar{u}) \]

\[ F_G(a.\bar{x}, \bar{u}; \bar{u}) = \begin{cases} 
  F_G(\bar{x}, \bar{x}; 1.\bar{u}) = 1 & \text{if } \text{hd}(\bar{x}) = 1 \\
  F_G(\bar{x}, \bar{x}; 0.\bar{u}) = 1 & \text{otherwise}
\end{cases} \]

The formal definition with safe recursion with digital substitutions of \( F_G \) is as follows,

\[ F_G(\epsilon, \bar{x}; \bar{u}) = f_M(\bar{x}; \bar{u}) \]

\[ F_G(a.\bar{x}, \bar{x}; \bar{u}) = \text{Select}(; \text{hd}(\bar{x}), \text{Select}(; F_G(\bar{x}, \bar{x}; \text{cons}(1, \bar{u})), 1), \\
  F_G(\bar{x}, \bar{x}; \text{cons}(0, \bar{u}))), \text{Select}(; F_G(\bar{x}, \bar{x}; \text{cons}(1, \bar{u})), F_G(\bar{x}, \bar{x}; \text{cons}(0, \bar{u})), 0)) \]

It is clear from the definition that \( F_G(\text{cons}(1, g_S(\bar{x}; )), \bar{x}; 0) \) decides whether \( \bar{x} \) belongs to \( G \).

It follows that \( F \) belongs to the set of safe recursive functions with digital substitutions.

The other direction of the proof is done by induction on the definition of \( F \). The only critical case is when \( F \) is defined with safe recursion with digital substitutions:

\[ F(\epsilon, \bar{x}; \bar{u}) = h(\bar{x}; \bar{u}) \]

\[ F(a.\bar{x}, \bar{x}; \bar{u}) = g(\bar{x}, \bar{x}; F(\bar{x}, \bar{x}; \sigma_1(\bar{u})), F(\bar{x}, \bar{x}; \sigma_2(\bar{u}))). \]

In this case the result follows from the following lemma.

**Lemma 5** The relation \( F(a.\bar{x}, \bar{x}; \bar{u}) = 1 \) can be reduced in polynomial time to a decision problem in \( (\Sigma_K^{2|\bar{x}|+2})^H \) where \( H \) is an oracle deciding \( h(\bar{u}; \bar{u}) = 1 \).

**Proof.** By induction on \(|\bar{x}|\). For \( \bar{x} = \epsilon \), it is a consequence of Theorem 1.

Assume \( \bar{x} \neq \epsilon \), and define:

\[ a_1 = \begin{cases} 
  1 & \text{if } \text{hd}(F(\bar{x}, \bar{x}; \sigma_1(\bar{u}))) = 1 \\
  0 & \text{otherwise}
\end{cases} \]

\[ a_2 = \begin{cases} 
  1 & \text{if } \text{hd}(F(\bar{x}, \bar{x}; \sigma_2(\bar{u}))) = 1 \\
  0 & \text{otherwise}
\end{cases} \]

Since \( g \) is a pseudo logical function, it is computable in constant time, and the value of \( F(a.\bar{x}, \bar{x}; \bar{u}) = g(\bar{x}, \bar{x}; F(\bar{x}, \bar{x}; \sigma_1(\bar{u})), F(\bar{x}, \bar{x}; \sigma_2(\bar{u}))) \) depends only on the relations \( \text{hd}(F(\bar{x}, \bar{x}; \sigma_1(\bar{u}))) = 1 \) and \( \text{hd}(F(\bar{x}, \bar{x}; \sigma_2(\bar{u}))) = 1 \). Thus,

\[ g(\bar{x}, \bar{x}; F(\bar{x}, \bar{x}; \sigma_1(\bar{u})), F(\bar{x}, \bar{x}; \sigma_2(\bar{u}))) = g(\bar{x}, \bar{x}; a_1, a_2). \]

Define

\[ F'(\bar{x}, \bar{x}; \bar{u}) = \begin{cases} 
  F(\bar{x}, \bar{x}; \sigma_1(\bar{u})) & \text{if } \text{hd}(\bar{c}) = 1 \\
  F(\bar{x}, \bar{x}; \sigma_2(\bar{u})) & \text{otherwise}
\end{cases} \]

Consider now the four possible values for \((a_1, a_2)\). The relation \( F(a.\bar{x}, \bar{x}; \bar{u}) = 1 \) is given by:
• \((a_1 = 1, a_2 = 1)\): \(\forall c \in \{1, 0\} (g(\overline{z}, \overline{x}; a_1, a_2) = 1) \land (F'(\overline{z}, \overline{x}; c, \overline{u}) = 1)\)

• \((a_1 = 1, a_2 = 0)\): \(\forall c \in \{1, 0\} (g(\overline{z}, \overline{x}; a_1, a_2) = 1) \land (c = 1 \iff F'(\overline{z}, \overline{x}; c, \overline{u}) = 1)\)

• \((a_1 = 0, a_2 = 1)\): \(\forall c \in \{1, 0\} (g(\overline{z}, \overline{x}; a_1, a_2) = 1) \land (c = 0 \iff F'(\overline{z}, \overline{x}; c, \overline{u}) = 1)\)

• \((a_1 = 0, a_2 = 0)\): \(\forall c \in \{1, 0\} (g(\overline{z}, \overline{x}; a_1, a_2) = 1) \land (F'(\overline{z}, \overline{x}; c, \overline{u}) \neq 1)\).

Note that the logical operations “\(\land\), \(\lor\), \(\iff\)” can be easily computed with the basic function \(\text{Select}\), projections and safe composition.

The relation \(F(a, \overline{z}, \overline{x}; \overline{u}) = 1\) is therefore given by

\[
\exists a_1, a_2 \in \{0, 1\}, \forall c \in \{0, 1\} \quad \begin{align*}
(g(\overline{z}, \overline{x}; a_1, a_2) = 1) \\
\land [((a_1 = 1 \land a_2 = 1) \land (F'(\overline{z}, \overline{x}; c, \overline{u}) = 1)) \\
\lor ((a_1 = 1 \land a_2 = 0) \land (c = 1 \iff F'(\overline{z}, \overline{x}; c, \overline{u}) = 1)) \\
\lor ((a_1 = 0 \land a_2 = 1) \land (c = 0 \iff F'(\overline{z}, \overline{x}; c, \overline{u}) = 1)) \\
\lor ((a_1 = 0 \land a_2 = 0) \land (F'(\overline{z}, \overline{x}; c, \overline{u}) \neq 1))].
\]

By induction hypothesis \(F(\overline{z}, \overline{x}; \overline{u}) = 1\) can be reduced to a decision problem in \((\Sigma^2_{\mathcal{K}})^H\), and therefore \(F'(\overline{z}, \overline{x}; c, \overline{u}) = 1\) can also be reduced to the same problem, which ends the proof.

\[\square\]

Remark 2 When \(\mathcal{K}\) is a finite structure, i.e., when considering classical complexity, this characterization coincides with our previous characterization of \(\text{PAR}_\mathcal{K}\) in [?], and captures \(\text{PSPACE}\).

9 Safe Recursion versus Simultaneous Safe Recursion

This section is devoted to the the proof that safe recursion yields the same algebras of function that simultaneous safe recursion.

**Proposition 1** The set of safe recursive functions over \(\mathcal{K}\) and the set of simultaneous safe recursive functions of [?] over \(\mathcal{K}\) coincide.

**Proof.** For the sake of simplicity, we prove this result for a double recursion scheme. The generalization to an arbitrary simultaneous recursion scheme stems on the same principles. We only need to prove that safe recursive functions can compute double safe recursive functions. The other direction is trivial. We proceed by induction on the definition tree. For basic safe functions, the result is trivial. For a function defined with safe composition, the induction hypothesis gives the result.
Assume that \( f_1, f_2 : (\mathbb{K}^*)^2 \times \mathbb{K}^* \rightarrow \mathbb{K}^* \) are defined by a double recursion scheme as follows:

\[
\begin{align*}
  f_1(\epsilon, \overline{x}; \overline{y}) &= h_1(\overline{x}; \overline{y}) \\
  f_2(\epsilon, \overline{x}; \overline{y}) &= h_2(\overline{x}; \overline{y}) \\
  f_1(\overline{a}; \overline{x}; \overline{y}) &= g_1(\overline{x}; f_1(\overline{a}; \overline{x}; \overline{y}), f_2(\overline{a}; \overline{x}; \overline{y}), \overline{y}) \\
  f_2(\overline{a}; \overline{x}; \overline{y}) &= g_2(\overline{x}; f_1(\overline{a}; \overline{x}; \overline{y}), f_2(\overline{a}; \overline{x}; \overline{y}), \overline{y})
\end{align*}
\]

The induction hypothesis allows us to assume that functions \( h_1, h_2, g_1, g_2 \) are safe recursive. Assume moreover that they respect the following homogeneous length hypothesis: there exists a safe recursive function \( L : (\mathbb{K}^*)^2 \rightarrow \{0\}^* \) such that, for all \( \overline{z}, \overline{x}, \overline{r}_1, \overline{r}_2, \overline{y} \in \mathbb{K}^* \),

\[
\begin{align*}
  |g_1(\overline{z}, \overline{x}; \overline{r}_1, \overline{r}_2, \overline{y})| &= |L(\overline{z}, \overline{x};)| \\
  |g_2(\overline{z}, \overline{x}; \overline{r}_1, \overline{r}_2, \overline{y})| &= |L(\overline{z}, \overline{x};)| \\
  |h_1(\overline{x}; \overline{y})| &= |L(\epsilon, \overline{x};)| \\
  |h_2(\overline{x}; \overline{y})| &= |L(\epsilon, \overline{x};)|.
\end{align*}
\]

This hypothesis allows us to define a function \( F : (\mathbb{K}^*)^2 \times \mathbb{K}^* \rightarrow \mathbb{K}^* \) such that:

\[
F(\overline{z}, \overline{x}; \overline{y}) = f_1(\overline{z}, \overline{x}; \overline{y}), f_2(\overline{z}, \overline{x}; \overline{y}).
\]

Let us define a safe recursive function \( p \) such that, for all \( \overline{x}, \overline{y}, \overline{m} \in \mathbb{K}^* \),

\[
\text{if } \overline{m} = \overline{m}_x.\overline{m}_y.\overline{m}_z \text{ and } |\overline{m}_x| = |\overline{x}|, |\overline{m}_y| = |\overline{y}| \text{ then } p(\overline{x}, \overline{y}; \overline{m}) = \overline{m}_y.
\]

This function realizes some kind of projection on \( \overline{m} \), and is formally defined with safe recursion as follows:

\[
\begin{align*}
  p(\epsilon, \overline{y}; \overline{m}) &= q(\overline{y}; \overline{m}) \\
  p(a.\overline{x}; \overline{y}; \overline{m}) &= \text{tl}(p(\overline{x}, \overline{y}; \overline{m})) \\
  q(\overline{y}; \overline{m}) &= q'(\overline{y}; q'(\overline{y}; \overline{m})) \\
  q'(\epsilon; \overline{m}) &= \epsilon \\
  q'(a.\overline{y}; \overline{m}) &= \text{cons}(\text{hd}(\text{Tl}(\overline{y}; \overline{m})), q'(\overline{y}; \overline{m})) \\
  \text{Tl}(\epsilon; \overline{m}) &= \overline{m} \\
  \text{Tl}(a.\overline{y}; \overline{m}) &= \text{tl}(\text{Tl}(\overline{y}; \overline{m})).
\end{align*}
\]

Let us also define a generalized concatenation \( \text{Cons} \) with safe recursion:

\[
\begin{align*}
  \text{Cons}(\overline{z}; \overline{x}; \overline{y}) &= \text{Cons}'(\overline{z}; q'(\overline{z}; \overline{x}); \overline{y}) \\
  \text{Cons}'(\epsilon; \overline{x}; \overline{y}) &= \overline{y} \\
  \text{Cons}'(a.\overline{x}; \overline{x}; \overline{y}) &= \text{cons}(\text{hd}(\text{Tl}(\overline{z}; \overline{x})), \text{Cons}'(\overline{z}; \overline{x}; \overline{y})).
\end{align*}
\]
\text{Cons}(\overline{z}; \overline{x}, \overline{y}) \text{ returns } \overline{x}; \overline{y} \text{ provided that } |\overline{z}| \geq |\overline{x}|. \text{ Let us detail now how we can formally define } F \text{ with safe recursion. Since } h_1, h_2, g_1 \text{ and } g_2 \text{ respect the homogeneous length hypothesis, we have:}

\begin{align*}
|h_1(\overline{x}; \overline{y})| & = |L(\epsilon, \overline{x})| \\
|h_2(\overline{x}; \overline{y})| & = |L(\epsilon, \overline{x})| \\
|f_1(\overline{z}, \overline{x}; \overline{y})| & = |L(tl'(\overline{z};), \overline{x};)| \text{ with } tl'(\overline{z};) = tl(\overline{z}) \\
|f_2(\overline{z}, \overline{x}; \overline{y})| & = |L(tl'(\overline{z};), \overline{x};)|.
\end{align*}

Thus, the definition of } F \text{ is:

\begin{align*}
F(\epsilon, \overline{x}; \overline{y}) & = \text{Cons}(L(\epsilon, \overline{x};); h_1(\overline{x}; \overline{y}), h_2(\overline{x}; \overline{y})) \\
F(a.\overline{x}, \overline{x}; \overline{y}) & = \text{Cons}(L(\overline{x}, \overline{x};); \\
& \quad g_1(\overline{x}, \overline{x}; p(\epsilon, L(tl'(\overline{z};), \overline{x};), F(\overline{z}, \overline{x}; \overline{y})), \\
& \quad p(L(tl'(\overline{z};), \overline{x};), L(tl'(\overline{z};), \overline{x}), F(\overline{z}, \overline{x}; \overline{y})), \overline{y}), \\
& \quad g_2(\overline{x}, \overline{x}; p(\epsilon, L(tl'(\overline{z};), \overline{x};), F(\overline{z}, \overline{x}; \overline{y})), \\
& \quad p(L(tl'(\overline{z};), \overline{x};), L(tl'(\overline{z};), \overline{x}), F(\overline{z}, \overline{x}; \overline{y})), \overline{y})).
\end{align*}

The rest of the proof follows from the following lemma.

**Lemma 6** For any safe recursive functions } f_1, f_2 : (K^*)^2 \times K^* \rightarrow K^* \text{ defined with double safe recursion, there exist safe recursive functions } f'_1, f'_2 : (K^*)^2 \times K^* \rightarrow K^* \text{ defined with double safe recursion with respect to the homogeneous length hypothesis and such that, for all } \overline{z}, \overline{x}, \overline{y} \in K^*, f'_1(\overline{z}, \overline{x}; \overline{y}) = f_1(\overline{z}, \overline{x}; \overline{y}) \text{ and } f'_2(\overline{z}, \overline{x}; \overline{y}) = f_2(\overline{z}, \overline{x}; \overline{y}).

**Proof.** Consider } f_1, f_2 : (K^*)^2 \times K^* \rightarrow K^* \text{ defined by a double recursion scheme as follows:

\begin{align*}
& f_1(\epsilon, \overline{x}; \overline{y}) = h_1(\overline{x}; \overline{y}) \\
& f_2(\epsilon, \overline{x}; \overline{y}) = h_2(\overline{x}; \overline{y}) \\
& f_1(a.\overline{x}, \overline{x}; \overline{y}) = g_1(\overline{x}, \overline{x}; f_1(\overline{z}, \overline{x}; \overline{y}), f_2(\overline{z}, \overline{x}; \overline{y}), \overline{y}) \\
& f_2(a.\overline{x}, \overline{x}; \overline{y}) = g_2(\overline{x}, \overline{x}; f_1(\overline{z}, \overline{x}; \overline{y}), f_2(\overline{z}, \overline{x}; \overline{y}), \overline{y}).
\end{align*}

Since they are computable in polynomial time, there exists a safe recursive function } B : (K^*)^2 \times K^* \rightarrow \{0\}^* \text{ such that:

\begin{align*}
\forall \overline{z}, \overline{x}, \overline{r}_1, \overline{r}_2 \overline{y} \in K^* \\
|g_1(\overline{z}, \overline{x}; \overline{r}_1, \overline{r}_2; \overline{y})| & < |B(\overline{z}, \overline{x};)| \\
|g_2(\overline{z}, \overline{x}; \overline{r}_1, \overline{r}_2; \overline{y})| & < |B(\overline{z}, \overline{x};)| \\
|h_1(\overline{x}; \overline{y})| & < |B(\epsilon, \overline{x};)| \\
|h_2(\overline{x}; \overline{y})| & < |B(\epsilon, \overline{x};)|.
\end{align*}
Let us define \( C : \mathbb{K}^* \times \mathbb{K}^* \to \mathbb{K}^* \) such that:

\[
C(\overline{b}; \overline{m}) = 1^{\overline{m}} \cdot 0^{|\overline{b}| - |\overline{m}|} \cdot \overline{m}
\]

and \( C^{-1} : \mathbb{K}^* \times \mathbb{K}^* \to \mathbb{K}^* \) such that:

\[
C^{-1}(\overline{b}; C(\overline{b}; \overline{m})) = \overline{m}.
\]

Note that \(|C(\overline{b}; \overline{m})| = 2|\overline{b}|\). These functions are formally defined as follows:

\[
C(\overline{b}; \overline{m}) = \text{Cons}(\overline{b}, q''(\overline{b}; \overline{m}), \text{Cons}(\overline{b}, q'''(\overline{b}; \overline{m}), \text{Cons}(\overline{b}, q''''(\overline{b}; \overline{m}), \overline{m})))
\]

\[
q''(\epsilon; \overline{m}) = \epsilon
\]

\[
q''(a; \overline{m}) = \begin{cases} q''(\overline{z}; \overline{m}) & \text{if } \text{hd}(\overline{z}; T(\overline{z}; \overline{m})) = \epsilon \\ \text{cons}(1, q''(\overline{z}; \overline{m})) & \text{otherwise} \end{cases}
\]

\[
q'''(\epsilon; \overline{m}) = \epsilon
\]

\[
q'''(a; \overline{m}) = \begin{cases} \text{cons}(0, q'''''(\overline{z}; \overline{m})) & \text{if } \text{tl}(\overline{z}; \overline{m}) = \epsilon \\ q''''(\overline{z}; \overline{m}) & \text{otherwise} \end{cases}
\]

\[
C^{-1}(\overline{b}; \overline{m}) = q'(\overline{b}; T(\overline{b}; \overline{m}'))
\]

\[
T(\epsilon, \overline{m}') = \epsilon
\]

\[
T(a; \overline{m}) = \begin{cases} \text{cons}(\text{hd}(\overline{z}; T(\overline{z}; \overline{m}')), T(\overline{z}; \overline{m}')) & \text{if } \text{hd}(\text{tl}(\overline{z}; \overline{m}'); \overline{m}')) = 1 \\ T(\overline{z}; \overline{m}) & \text{otherwise} \end{cases}
\]

\[
\text{Sub}(\overline{z}; \overline{t}) = \text{tl}(\text{tl}(\overline{z}; \overline{t})).
\]

It is obvious that the matching cases in these definition can be formally defined with the test function \textbf{Select}. These functions are therefore safe recursive. Define now by double safe recursion:

\[
f_1''(\epsilon; \overline{x}; \overline{y}) = C(B(\epsilon, \overline{x})); h_1(\overline{x}; \overline{y})
\]

\[
f_1''(a; \overline{x}, \overline{x}; \overline{y}) = C(B(\overline{x}, \overline{x}); g_1(\overline{x}, \overline{x}; C^{-1}(B(\text{tl}(\overline{x}; \overline{x}); \overline{x}; f_1''(\overline{x}, \overline{x}; \overline{y}))), C^{-1}(B(\text{tl}(\overline{x}; \overline{x}); \overline{x}; f_2''(\overline{x}, \overline{x}; \overline{y})), \overline{y}))
\]

\[
f_2''(\epsilon; \overline{x}; \overline{y}) = C(B(\epsilon, \overline{x}); h_2(\overline{x}; \overline{y}))
\]

\[
f_1''(a; \overline{x}, \overline{x}; \overline{y}) = C(B(\overline{x}, \overline{x}); g_2(\overline{x}, \overline{x}; C^{-1}(B(\text{tl}(\overline{x}; \overline{x}); \overline{x}; f_1''(\overline{x}, \overline{x}; \overline{y}))), C^{-1}(B(\text{tl}(\overline{x}; \overline{x}); \overline{x}; f_2''(\overline{x}, \overline{x}; \overline{y})), \overline{y})).
\]

Then \( f_1' \) and \( f_2' \) are given by

\[
f_1'(\overline{x}; \overline{x}; \overline{y}) = C^{-1}(B(\overline{x}, \overline{x}); f_1''(\overline{x}, \overline{x})))
\]

\[
f_2'(\overline{x}; \overline{x}; \overline{y}) = C^{-1}(B(\overline{x}, \overline{x}); f_2''(\overline{x}, \overline{x}))).
\]
