**Abstract:** As increasing variants of nanoparticles (NPs) are being used in various products, it has become apparent that size alone can no longer adequately explain the variety of generated toxic profiles. Recent studies with NPs have suggested that various sizes of NPs could determine in vitro toxicity. In an attempt to address concerns regarding neurotoxicity of zinc oxide (ZnO) and silica (SiO<sub>2</sub>) NPs, these were examined after exposing them via oral, dermal, and intravenous administrations of NPs and their toxicological effects on the brain over a prescribed period of time were assessed. After 28 days of repeated oral administrations of ZnO or SiO<sub>2</sub> independently, possibly due to damages to the blood brain barrier (BBB), neurotoxicity, were investigated by Evans blue technique. Next, in order to assess whether ZnO NPs could compromise the BBB, ZnO NPs were intravenously injected on day 0, 7, 14, 21 and 28 no further treatment was administered for 62 days. Deposition of SiO<sub>2</sub> in brain from repeated dermal and oral administrations for 90 days were evaluated by transmission electron microscopy coupled with scanning energy-dispersive X-ray spectroscopy. Physiochemical profiles were principally determined on particle size at the beginning of the current toxicity investigations on ZnO and SiO<sub>2</sub> NPs. The BBB was found to be intact after independent repeated oral administrations of ZnO or SiO<sub>2</sub> NPs for 28 days, suggesting no significant damage. Neuronal death was also not observed after the intravenous administrations of ZnO NPs. After 90 days of repeated dermal and oral administration of SiO<sub>2</sub> NPs, no deposition of NPs was observed in hippocampus, striatum, and cerebellum regions using transmission electron microscope analyses. These observations suggest that the BBB was not compromised and was able to block penetration of ZnO and SiO<sub>2</sub> NPs, resulting in significant neurotoxic effects. Moreover, absence of SiO<sub>2</sub> in three regions of brain after dermal and oral administrations for 90 days suggested that brain was protected from SiO<sub>2</sub>. No behavior change was observed in all studies, suggesting that 90 days may not be long enough to assess full neurotoxicity of NPs in vivo.

**Keywords:** zinc oxide, silica, BBB, neurotoxicity, penetration, administration

## Introduction

Potential toxicities of nanoparticles (NPs) are of growing concern in academia and for regulatory agencies, industries, and society. This, in turn, has prompted a flurry of new studies and the expansion of smaller investigations in regards to the neurotoxicity of NPs in vivo. As precise understanding of NPs toxicity remains elusive, many developed countries have recently embarked on a concerted effort to further update the in vivo toxicity profile of many different types of NPs in everyday use.

One of the oldest and most frequently used NPs is zinc oxide (ZnO). ZnO NPs are present in sunscreens and cosmetic products due to their role in preventing skin cancers by protection from ultraviolet light, and promoting pH balance, and flora regeneration.

Silica (SiO<sub>2</sub>) NPs can be found in abrasives, food additives, cosmetics, and biomedical devices. Their use in the medical field in diagnosis, imaging, and drug delivery is on the rise. According to recent reports, inhaled NPs could travel to brain or systemically via lung or olfactory nerves on the upper section of the nasal cavity.<sup>1</sup> Furthermore, direct injections of NPs to brain have been shown to cause inflammation and neurotoxicity, leading to neurological diseases.<sup>2-5</sup>

In *in vitro* studies, ZnO NPs caused apoptosis of neural stem cells and interfered with the ion channel current in primary hippocampal neurons from rat.<sup>6,7</sup> Moreover, ZnO NPs in association with the onset of neurological diseases was recently reported.<sup>8</sup> In the case of SiO<sub>2</sub> NPs, accumulations in liver and spleen causing necrosis have been observed.<sup>9</sup> In addition, inhalation studies with SiO<sub>2</sub> NPs showed penetration of NPs into brain through the nasal cavity, leading to accumulations in the striatum, causing oxidative damages and inflammatory responses.<sup>10</sup> Hence, it is possible that the accumulation of these NPs in brain may reduce dopamine generation and protein downregulation of tyrosine hydroxylase, which can lead to Parkinson's disease.

The blood-brain barrier (BBB) is an important physical barrier for controlling homeostasis and stopping the transmission of foreign substances into the central nervous system. Based on *in vivo* studies, NPs in blood may cause damage to the BBB and increase overall permeability, leading to BBB disruption and penetration of NPs, causing neurological diseases.<sup>11,12</sup> Previously, damage to the BBB was measured using Evans blue dye (Sigma-Aldrich Co., St Louis, MO, USA) after injections of 50–60 nm silver (Ag), aluminum (Al), and copper (Cu) NPs via intravenous, intraperitoneal, or intracerebral routes.<sup>13</sup> Evans blue dye is suitable for assessing BBB damage by chemicals or NPs and has high affinity with albumin, making the dye visible in the brain or its homogenates upon BBB disruption.

After titanium dioxide NPs were repeatedly injected intranasally for 30 days, they were observed in the hippocampus, leading to obvious morphological changes with increased expressions of glial fibrillary acidic protein.<sup>14</sup> Recent studies also reported that Fe<sub>3</sub>O<sub>4</sub> NPs (30 nm) could move directly from the olfactory nerve to the brain after intranasal administrations, where NPs could be found in the striatum and hippocampus.<sup>15</sup> Previously, SiO<sub>2</sub>-coated magnetic NPs were found in the brain following intraperitoneal administration.<sup>16</sup> In order to monitor the passage of NPs after intraperitoneal administration, PEGylated fluorescein-doped magnetic SiO<sub>2</sub> NPs was moved through astrocytes of the BBB from vascular endothelial cells to cerebral parenchyma.<sup>17</sup> In addition, 70 nm SiO<sub>2</sub> NPs were

observed in cerebral cortex and hippocampus after dermal exposure for 28 days.<sup>18</sup> After exposure of NPs to rats for 6 hours in a whole-body exposure chamber, the concentration of NPs was significantly increased in the cerebrum and cerebellum, but the increase was transient for only 1 additional day of the post-exposure period.<sup>19</sup> It seems that insoluble or poorly soluble NPs could enter the brain via the olfactory neuronal pathway and through the BBB.<sup>20</sup> Hence, the above results suggest potential neurotoxicity of NPs and the cause of neurodegenerative diseases by the accumulation of NPs in the brain.

In previous studies, bound plasma proteins or protein corona onto both ZnO and SiO<sub>2</sub> NPs were identified. Interestingly, apolipoprotein E was found to bind to NPs, and the interaction may help NPs to pass through the BBB as part of a complex. Hence, disruptions of BBB by ZnO and SiO<sub>2</sub> NPs was investigated and evaluated by Evans blue after oral administrations of NPs for 28 days. In addition, immunohistochemistry (IHC) analyses were performed to confirm inflammations in specific regions of the brain after 90 days of transdermal and oral administrations NPs.

## Materials and methods

### Preparation of NPs

Different sizes of ZnO nanomaterials were purchased from Sumitomo Osaka Cement Co, Ltd, (lot no 141319 for 20 nm; Tokyo, Japan) and American Elements (lot no 1871511079-673 for 100 nm; Los Angeles, CA, USA). Modifications of purchased ZnO NPs were progressed to change the surface charge using coating reagents, citrate (for negative charge), and L-serine (for positive charge) as reported previously.<sup>21</sup>

SiO<sub>2</sub> nanomaterials (20 and 100 nm) were obtained from E&B Nanotech Co, Ltd, (Ansan, Republic of Korea). L-arginine was used to increase the number of available protonated silanol groups on the surface of SiO<sub>2</sub> NPs.<sup>22</sup> The physicochemical properties were verified, including their average sizes and morphology and zeta potentials.<sup>21,22</sup>

### Evaluation of BBB damage

#### by NPs with Evans blue

##### Oral administration

Rats (5 weeks old) were acclimatized for 1 week, and five rats of similar weight were selected for each group. Administration volume of NPs was determined by measuring the average weight of rats every week (Table 1). The dosages for each route of administration were determined from a 14-day repeated-dose study (Yu-Ri Kim, unpublished data, 2014). According to previous results, the maximum dose for causing significant systemic toxicity was selected for each group.

**Table 1** Administration concentrations and volumes of 28-day repeated oral administrations in rats

Experimental group	Test material	Sex	Number of animals	Administration concentration (mg/kg)	Administration volume (mL/kg)
Group 1 (negative control)	Distilled water	Female	5	0	10
Group 2 (diluting agent)	HEPES-citrate buffer	Female	5	0	10
Group 3 (diluting agent)	HEPES-serine buffer	Female	5	0	10
Group 4 (diluting agent)	L-arginine	Female	5	0	10
Group 5 (high volume)	ZnO (20 nm, – charge)	Female	5	500	10
Group 6 (high volume)	ZnO (20 nm, + charge)	Female	5	500	10
Group 7 (high volume)	SiO <sub>2</sub> (20 nm, – charge)	Female	5	2,000	10
Group 8 (high volume)	SiO <sub>2</sub> (20 nm, + charge)	Female	5	1,000	10

**Abbreviations:** HEPES, (4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid); ZnO, zinc oxide; SiO<sub>2</sub>, silica.

### Evans blue procedure

After 28 days of repeated oral administrations, animals were anesthetized with isoflurane. Evans blue solution (2% solution 4 mL/kg) was injected via the tail vein and circulated for 1 hour. After the second anesthetization, animals were perfused with saline to remove the intravascular dye through the coronary artery, and paraformaldehyde (4%) was used to perfuse the brain. Brain was extracted, divided into left brain, right brain, and cerebellum, and the weight of each of these brain sections was measured. Each brain section was incubated with formamide at 55°C for 24 hours. The supernatant was separated after centrifugation at 12,000 g for 20 minutes. A spectrophotometer (VICTOR™ x5; PerkinElmer, Waltham, MA, USA) was used to measure absorbance at 635 nm.

### Evaluating inflammation responses after NPs

#### Intravenous administration of ZnO NPs by IHC analysis

All four types of ZnO NPs (positively/negatively charged 20 nm and 100 nm NPs) at 0.1, 10 mg/animal of 20 and 100 nm respectively, were injected intravenously into the tail of the animal for 90 days. After 90 days, animals were euthanized and whole brains were obtained immediately for IHC testing.

#### IHC

Left hemispheres of brain were immersed in 30% formaldehyde and fixation through tissue dehydration with ethyl alcohol and xylene. The tissues were sectioned to 6 mm thick using a microtome (Dako, RM2155 Microtome; Leica, Germany) and fixed on glass slides. First, deparaffinizing was performed. Next, endogenous peroxidase inhibitor was treated to each section and incubated for 30 minutes at room temperature. Biotin blocker was then added and incubated for 30 minutes at room temperature. The slides were immersed in Seablock (Thermo Fisher Scientific, Waltham, MA, USA),

a blocking agent, for 30 minutes, and biotinylated NeuN antibody (EMD Millipore, Billerica, MA, USA) was used to treat the section for 1 hour as per the manufacturer's recommendations (100 times dilution). The washing step was repeated two times with phosphate-buffered saline (PBS) for 5 minutes, and horseradish peroxidase-conjugated NeutrAvidin was incubated on the tissue sections at concentrations of 10 µg/mL in PBS. After following the same washing procedure, NeuN protein was visualized with diaminobenzidine plus chromogen for 5 minutes and rinsed with PBS three times prior to counterstaining. The sections were immersed in Mayer's hematoxylin solution for 2 minutes and rinsed with tap water until the color of tissues turned blue. The sections were dehydrated in ethyl alcohol for mounting using Dako's Mounting Medium. The tissues from the cerebellum regions were analyzed with a Nikon microscope (Eclipse TE2000-U; Nikon Corporation, Tokyo, Japan).

#### SiO<sub>2</sub> NP accumulation in rat brain after repeated administration

SiO<sub>2</sub><sup>EN100(R)</sup> and SiO<sub>2</sub><sup>EN20(R)</sup> were orally administered to animals, and SiO<sub>2</sub><sup>EN100(-)</sup> and SiO<sub>2</sub><sup>EN20(-)</sup> were dermally administered to animals (Table 2). After animals were anesthetized by isoflurane, the blood in both blood vessel and the brain was removed by perfusing saline through coronary artery. Paraformaldehyde solution (1%) was injected into the coronary artery to perfuse the brain, and the extracted brain was

**Table 2** Administration concentrations and volumes for 90-day SiO<sub>2</sub><sup>EN100(R)</sup> and SiO<sub>2</sub><sup>EN20(R)</sup> oral administrations and SiO<sub>2</sub><sup>EN100(-)</sup> and SiO<sub>2</sub><sup>EN20(-)</sup> dermal administrations

Method	Test material	Administration concentration (mg/kg)	Administration volume (mL/kg)
Oral administration	SiO <sub>2</sub> <sup>EN20(R)</sup>	1,000	10
	SiO <sub>2</sub> <sup>EN100(R)</sup>	1,000	10
Dermal administration	SiO <sub>2</sub> <sup>EN20(-)</sup>	2,000	10
	SiO <sub>2</sub> <sup>EN100(-)</sup>	2,000	10

washed in 4% paraformaldehyde. The brain was divided into hippocampus, striatum, and cerebellum using a razor blade to cut into the size of 1 mm<sup>3</sup>. Each region was stored in a vial containing 4% paraformaldehyde.

Small pieces of brain sample were dissected and washed three times with PBS. For postfixation, samples were placed in sodium cacodylate-buffered 1.5% osmium tetroxide for 60 minutes at 4°C before staining with the blocking agent uranyl acetate (0.5%). Brain samples were dehydrated via a series of ethanol concentrations and embedded in Epon resin (TAAB Laboratories Equipment Ltd, Aldermaston, UK). Uranyl acetate and lead citrate were used for staining ultrathin sections. An Hitachi electron microscope (H-7650; Hitachi Ltd, Tokyo, Japan) was used for the examination.

## Results

### Assessing damage to the BBB by NPs using Evans blue

Evans blue was dissolved in formamide, and then the solution was serially diluted to obtain a standard curve at a wavelength of 635 nm (Figure 1). The amount of Evans blue (μg) in the brain (g) was calculated from the optical density (OD) value of extracted brain using the formula from the standard curve (Figure 1).

The brain extracted from rats treated with ZnO NPs was cut into right brain, left brain, and cerebellum. Then, Evans blue from each area of the brain was extracted with formamide solution, and measured OD at 635 nm wavelength. The amount of Evans blue was calculated using the stated formula according to the standard curve (Figure 1). Groups treated with NPs were measured higher OD values in comparison to the control group, but the standard deviations were high and the difference between positive and negative

**Figure 1** Standard curve of Evans blue.

**Note:** Evans blue dye (Sigma-Aldrich Co., St Louis, MO, USA).

**Abbreviation:** OD, optical density.

control samples was not statistically significant (Figure 2A). After the quantification from OD to the amount of Evans blue (μg)/g, all experimental groups showed the amount of extracted Evans blue from NPs treated rats (positive group) was higher than the negative control group. However the standard deviations were high and the difference between positive and negative control samples was not statistically significant. (Figure 2B).

The OD of extracted formamide solution from the brain of SiO<sub>2</sub>-treated animals was measured. The measured value of OD was used to calculate the amount of Evans blue (μg) in the brain (g) (Figure 3B). Significance was displayed with SiO<sub>2</sub><sup>EN20(R)</sup>-treated group than the control group, but the value of the treated group was lower than that of the control group. Also, no significant difference was seen between negative control groups and NPs treated groups (Figure 3A). Similarly, there was no significant difference in the amount of Evans blue for all samples (Figure 3B).

### IHC

The brains of animals were investigated by IHC method with NeuN-specific staining with Mayer's hematoxylin counterstaining. In particular, cerebellums of the rats were examined for structural changes, and differences were compared to the normal control. Neuronal cells were stained specifically by using NeuN-specific antibody, and no morphological change was observed from ZnO NPs injected groups through animal's tail vein in comparison to PBS-treated control group. No observable changes in brain slices were found in the rats treated with ZnO NPs of different sizes, surface charges, and concentrations (Figure 4).

### Observation of accumulation of NPs in the brain of the repeatedly administered rats using transmission electron microscopy (TEM)

First, as a positive control test, SH-SY5Y neuroblastoma cells were incubated with SiO<sub>2</sub> NPs (100 nm) in vitro, then NPs were observed using TEM (Figure 5A). The size of the NPs was confirmed to be 100 nm, and a silicon (Si) peak (1.7 KeV) was verified using an energy-dispersive X-ray spectroscope (EDS) (Figure 5B).

Each group treated with SiO<sub>2</sub> NPs was monitored for the presence of NPs in cerebellum, hippocampus, and striatum using TEM after dermal administration of SiO<sub>2</sub><sup>EN20(-)</sup> and SiO<sub>2</sub><sup>EN100(-)</sup> and oral administration of SiO<sub>2</sub><sup>EN20(R)</sup> and SiO<sub>2</sub><sup>EN100(R)</sup>. After 90 days of repeated administrations, the brain was extracted and cut to 1 mm<sup>2</sup> fragments and

**Figure 2** The difference value between ZnO NP treated groups and control groups.

transported to the Korea Institute of Science and Technology (Seoul, Republic of Korea) for TEM analyses. Cerebellum, hippocampus, and striatum were investigated thoroughly, since the accumulation of NPs was expected to occur in those brain areas (Figure 6). Nano-size dots were observed in each brain region, and EDS analysis was performed to confirm the presence or absence of SiO<sub>2</sub> NPs. According to EDS analysis, the Si peak was absent and only osmium and lead (dye materials) and carbon and Cu (grid materials) peaks were present, belonging to the pretreatment chemicals (Figure 7A). In addition, a suspected iron peak was observed, which could have been from the blood vessel in the brain (Figure 7B). In SiO<sub>2</sub><sup>EN100(-)</sup> group, suspected nano-size dot was analyzed to conform silica NPs. However no silica peak appeared in the EDS graph (Figure 8).

## Discussion

Recently, the composition of protein corona on the surface of ZnO or SiO<sub>2</sub> NPs from incubation with plasma and brain homogenates was analyzed. Interestingly, apolipoproteins were found in abundance, and other proteins involved in

inflammation and complement activations were also detected. Apolipoprotein E was also present, which is known to mediate the passing of NPs across the BBB and to be involved in Alzheimer's disease.<sup>23,24</sup>

Previous studies with rat animal models reported that Ag, Cu, and Al NPs induced BBB damages and disruptions and brain edema formation after repeated exposure by intravenous, intraperitoneal, and intracerebral administrations.<sup>13</sup> In the current study, Evans blue analysis was performed to investigate BBB disruption from repeated oral administrations of ZnO and SiO<sub>2</sub> NPs for 28 days. Unlike previous results with Ag, Cu, and Al NPs,<sup>13</sup> a significant difference was not observed in the brains of rats treated with ZnO or SiO<sub>2</sub> NPs in comparison with the normal control group. This result suggests that the repeated oral administration of ZnO or SiO<sub>2</sub> NPs for 28 days did not induce BBB damage. In the case of oral administration, only a small percentage of NPs seemed to be absorbed through intestine.<sup>25,26</sup> Hence, BBB damage may not have been induced because the small amount of penetrated NPs from intestine to the blood vessel could have been cleared away by liver and kidney.

**Figure 3** The difference value between SiO<sub>2</sub> NP treated groups and control groups.

(A) Phosphate-buffered saline-injected control normal rat brain of cerebellum region; (B) 10 mg of  $\text{ZnO}^{\text{SM20}(+)}$ ; (C) 0.1 mg of  $\text{ZnO}^{\text{SM20}(+)}$ ; (D) 10 mg of  $\text{ZnO}^{\text{SM20}(-)}$ ; (E) 0.1 mg of  $\text{ZnO}^{\text{SM20}(-)}$ ; (F) 10 mg of  $\text{ZnO}^{\text{SM100}(+)}$ ; (G) 0.1 mg of  $\text{ZnO}^{\text{SM100}(+)}$ ; (H) 10 mg of  $\text{ZnO}^{\text{SM100}(-)}$ ; (I) 0.1 mg of  $\text{ZnO}^{\text{SM100}(-)}$ .

Several studies have reported that insoluble or poorly soluble NPs could enter the brain via the olfactory neuronal pathway and through the BBB.<sup>20</sup> Consequently, BBB-penetrated NPs could cause several cellular and molecular events, such as oxidative and heat stresses.<sup>10,27,28</sup> The exposure to NP-rich diesel exhausts has been found to upregulate messenger (m)RNA levels of proinflammatory cytokines and N-methyl-D-aspartate receptor subunits in the hippocampus.<sup>29</sup> However, the exposure of the lactoferrin-conjugated polyethylene glycol-poly lactide-polyglycolide NPs showed no inflammatory reaction in the brain.<sup>30</sup> In our study, no morphological change was found in the cerebellum after ZnO NP injections through the tail vein. However, further

investigations should be performed in order to fully rule out the potential for neurotoxicity with long-term exposures.

Dermal and oral administrations of  $\text{SiO}_2$  NPs were performed for 90 days to confirm whether NPs were deposited in the brain upon penetrating the BBB, and the specific areas of the brain (hippocampus, striatum, and cerebellum), were performed by the analysis as per other reports.<sup>15,16,18</sup> After 90 days of administrations, deposition of NPs was not found in any region of the brain. Nano-size dots were analyzed by EDS to know whether it is the aggregated dye materials. Based on other reports of intranasal administration of NPs, they were found mostly in the hippocampus, striatum, and cerebellum.<sup>1,10,15,16</sup> After intranasal exposure, NPs can be

directly transported from the nose to the brain via the olfactory nerve.<sup>20</sup> However, NPs administered dermally or orally should penetrate skin or intestine wall, respectively, and NPs also need to penetrate the BBB to reach the brain. Hence, it was suggested that NPs in blood may not reach the brain after dermal and oral administrations. In previous studies, NPs were deposited mainly in lung, liver, spleen, and kidney after administrations.<sup>9,14,19</sup> The majority of  $\text{SiO}_2$  NPs were excreted via feces, and 7%–8% of particles were excreted via urine (Jeong-A Lee, unpublished, 2014). Additionally, positron emission tomography analysis of  $\text{SiO}_2$  NPs revealed that they had not accumulated significantly in the brain, indicating that NPs may not have penetrated the BBB and did not deposit in the brain (Chang-Moon Lee, unpublished, 2014).

## Conclusion

According to the preliminary data, oral administration of ZnO and  $\text{SiO}_2$  NPs for 90 days did not compromise or damage the BBB. Intravenous injections of ZnO NPs showed no toxic effect in the brain, and exposure to  $\text{SiO}_2$  NPs by dermal and oral administrations over the same period showed a complete absence of silica particulates in all of the samples analyzed by TEM. These results suggest that oral and dermal administrations of ZnO and  $\text{SiO}_2$  NPs do not induce significant neurotoxic effects in the brain.

### International Journal of Nanomedicine

### Publish your work in this journal

The International Journal of Nanomedicine is an international, peer-reviewed journal focusing on the application of nanotechnology in diagnostics, therapeutics, and drug delivery systems throughout the biomedical field. This journal is indexed on PubMed Central, MedLine, CAS, SciSearch®, Current Contents®/Clinical Medicine,

Submit your manuscript here: <http://www.dovepress.com/international-journal-of-nanomedicine-journal>

Dovepress

Journal Citation Reports/Science Edition, EMBase, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
