Artificial Neural Network Controlled DSTATCOM for Power Quality Improvement

S. Sherin Jasper
M.E. Department of Power electronics and drives, Sri Shakthi Institute of engineering and technology, Coimbatore, Tamil Nadu. India

Abstract: The paper intends to develop the artificial neural network control algorithm for the control of DSTATCOM for the improvement of power quality. The presence of nonlinear loads makes the voltage to be deviated and current to be distorted from its sinusoidal waveform quality. Thus harmonics elimination, load balancing and voltage regulation is the heavy task that has to be accomplished to maintain the quality of the power. The performance of any device depends on the control algorithm used for the reference current estimation and gating pulse generation scheme. Thus the artificial neural network based Back Propagation (BP) algorithm has been proposed to generate the triggering pulses for the three phase H bridge inverter (DSTATCOM). The fundamental weighted value of active and reactive power components of load currents which are required for the estimation of reference source current is calculated by using BP-based control algorithm. Based on the difference of the target voltage and the generated voltage, the triggering pulse for the inverter is obtained by the BP algorithm. Then the voltage is injected at the point of common coupling to compensate the reactive power. Thus by regulating the voltage and compensation of reactive power, the power quality can be improved. The simulation modelling of the Back propagation algorithm controlled DSTATCOM and the PWM controlled DSTATCOM and the comparative analysis of the algorithms is presented in this paper.

Index Term: DSTATCOM, Artificial Neural Network, Back propagation (BP) control algorithm, Reference current Estimation, Power quality.

I. MOTIVATION

Power quality in distribution systems affects all the electrical and electronics equipment that are connected. This measures the deviation in the measurement of frequency, current and Voltage of the system. The use of power converters in power supplies, adjustable speed drives, is continuously increasing in recent years. This equipment draws harmonics currents from AC mains and increases the supply demands. The classification of loads includes linear (lagging power factor loads), nonlinear (current or voltage source type of harmonic generating loads), unbalanced and mixed types of loads. The power quality problems associated with these loads include, load unbalancing, harmonics, high reactive power burden, voltage variation.

The power quality problems are compensated in a distribution system by the Custom Power devices. These custom power devices are classified as the DSTATCOM (Distribution Static Compensator), DVR (Dynamic Voltage Restorer) and UPQC (Unified Power Quality Conditioner). The power quality at the Point of common coupling is governed by standards such as IECSC77A , IEEE-519-1992, IEEE-1531-2003 and IEC- 61000, etc.

The block diagram of the proposed system consists of the three phase supply supplying the nonlinear load, DSTATCOM block, interfacing inductor, and the DSTATCOM controller. The DSTATCOM controller used in this project is the Back Propagation method, which is the neural network controlled algorithm.

The effectiveness of DSTATCOM depends upon the control algorithm used for generating the switching signals for the voltage source converter and value of interfacing inductors. Many control algorithms are reported in the literature based on the instantaneous reactive power theory, deadbeat or predictive control instantaneous symmetrical component theory nonlinear control technique, modified power balance theory, enhanced phase locked loop technique, Adaline control technique, synchronous reference frame control technique, ANN and fuzzy based controller, SVM based controller, correlation and cross-correlation coefficients based control algorithm for the control of DSTATCOM. In this Paper, the designed system will be applied to detect transient voltage in electrical power systems. The problem of power quality is detected by artificial neural network based BP algorithm. The performance of the designed system will be tested through a simulation platform designed in MATLAB/Simulink.

II. BLOCK DIAGRAM OF ANN CONTROLLED DSTATCOM

Figure 1: Block diagram of the ANN controlled DSTATCOM
III. DSTATCOM

The D-STATCOM is a three phase shunt connected reactive power compensation equipment, whose output can be varied so as to maintain control of specific parameters of the electric power system by the generation and/or absorption of the reactive power. The D-STATCOM consists of three phase GTO/IGBT voltage source inverter (VSI), a coupling transformer with a leakage reactance and DC capacitor. The DSTATCOM topologies can be classified based on of switching devices, use of transformers for isolation, use of transformers for neutral current compensation.

The ac voltage difference across the leakage reactance power exchange between the Power system and the DSTATCOM at the bus bar can be regulated to improve the voltage profile of the power system. This constitutes the primary duty of the DSTATCOM. However a secondary damping function is added in to the D-STATCOM for enhancing power system oscillation stability.

The D-STATCOM employs solid state power switching devices and provides rapid controllability of magnitude and the phase angle of the phase voltages. The D-STATCOM provides operating characteristics that of the rotating Synchronous compensator without the mechanical inertia. The D-STATCOM has an inverter to convert the DC link voltage $V_{dc}$ on the capacitor to a voltage source of adjustable phase and magnitude. Therefore the D-STATCOM can be treated as a voltage controlled source or current controlled source.

The DSTATCOM currents ($i_{Cabc}$) are injected as required compensating currents to cancel the reactive power components and harmonics of the load currents so that loading due to reactive power component/harmonics is reduced on the distribution system. The controller of the D-STATCOM is used to operate the inverter in such a way that the phase angle between the inverter voltage and the line voltage is dynamically adjusted so that the D-STATCOM generates or absorbs the desired VAR at the point of connection. The phase of the output voltage of the inverter $V_i$, is controlled in the same way as the distribution system voltage.

The controller of the D-STATCOM is used to operate the inverter in such a way that the phase angle between the inverter voltage and the line voltage is dynamically adjusted so that the D-STATCOM generates or absorbs the desired VAR at the point of connection. The phase of the output voltage of the inverter $V_i$, is controlled in the same way as the distribution system voltage.

The DSTATCOM is operated for the compensation of lagging power factor balanced load to correct the power factor at source side or to regulate the voltage at PCC. In ZVR mode, DSTATCOM injects currents to regulate the PCC voltage at the desired reference value of the voltage and the source currents may be leading or lagging currents depending on the reference value of PCC voltage.

The three basic operation modes of the D-STATCOM for the output current, $I_y$ vary depending upon $V_i$. The DSTATCOM currents ($i_{Cabc}$) are injected as required compensating currents to cancel the reactive power components and harmonics of the load currents so that loading due to reactive power component/harmonics is reduced on the distribution system. The controller of the D-STATCOM is used to operate the inverter in such a way that the phase angle between the inverter voltage and the line voltage is dynamically adjusted so that the D-STATCOM generates or absorbs the desired VAR at the point of connection. The phase of the output voltage of the inverter $V_i$, is controlled in the same way as the distribution system voltage.
IV. DSTATCOM VOLTAGE CONTROLLER

The aim of the control scheme is to maintain constant voltage magnitude at the point where a sensitive load is connected. The control system only measures the r.m.s. voltage at the load point, i.e., no reactive power measurements are required. The VSC switching order is based on a sinusoidal PWM technique which offers simplicity and good response. PWM methods offer a more flexible option for a low power application which is the existing system. Thus the new approach of using the artificial neural network controlled controller for DSTATCOM is proposed in this project.

A. EXISTING SYSTEM: Sinusoidal Pulse Width Modulation control

In pulse width modulation control, the converter switches are turned on and off several times during a half cycle and the output voltage is controlled by varying the width of the pulses. The gate signals are generated by comparing a triangular wave with a DC signal. The lower order harmonics can be eliminated or reduced by selecting the number of pulses per half cycle. However increasing the number of pulses would also increase the magnitude of higher order harmonics which could easily be filtered out.

The width of the pulses can be varied to control the output voltage. However the pulse width of pulses could be different. It is possible to choose the widths of pulses in such a way that certain harmonics can be eliminated. The most common way of varying the width of the pulses is the Sinusoidal Pulse Width Modulation. In SPWM the displacement factor is unity and the power factor is improved. The lower order harmonics are eliminated and reduced. The SPWM pulses are generated and the DSTATCOM was controlled in the open loop response.

B. PROPOSED SYSTEM: Artificial Neural architecture

A BP algorithm is implemented in a three phase shunt connected custom power device known as DSTATCOM for the extraction of the weighted value of load active power and reactive power current components in nonlinear loads. The BP algorithm is used for harmonic suppression and load balancing in PFC and zero voltage regulation (ZVR) modes with dc voltage regulation of DSTATCOM. In this BP algorithm, the training of weights has three stages:

- Feed forward of the input signal training,
- Calculation and BP of the error signals,
- Upgrading of training weights.

The BP algorithm has one or more than one layer. It is based on a mathematical formula and does not need special features of function in the learning process. It also has smooth variation on weight correction due to batch updating features on weights. It is slow during the training process due to more number of learning steps, but after the training of weights, the algorithm produces very fast trained output response. Continuity, non-decreasing monotony and differentiability are the main characteristics of BP algorithm. In this application, the proposed control algorithm on a DSTATCOM is implemented for the compensation of nonlinear loads.

The initial output pattern is compared with the desired output pattern and the weights are adjusted by the algorithm to minimize the error. The iterative process finishes when the error becomes near null.

REFERENCE CURRENT GENERATION

A BP training algorithm is used to estimate the three phase weighted value of load active power current components (\(w_{ap}, w_{bp}\) and \(w_{cp}\)) and reactive power current components (\(w_{aq}, w_{bq}\) and \(w_{cq}\)) from polluted load currents using the feed forward and supervised principle.

A. DERIVATION OF REFERENCE CURRENTS

In this estimation, the input layer for three phases (a, b, and c) is expressed as

\[I_{ap} = w_{ap} + i_{ap} + i_{bp} + i_{cp}\]

\[I_{bp} = w_{bp} + i_{ap} + i_{bp} + i_{cp}\]

\[I_{cp} = w_{cp} + i_{ap} + i_{bp} + i_{cp}\]

Figure 5: Proposed modeling of BP algorithm
Where \( w_o \) is the selected value of the initial weight and \( u_{ap} \), \( u_{bp} \), and \( u_{cp} \) are the in-phase unit templates.

In-phase unit templates are estimated using sensed PCC phase voltages (\( V_{ap} \), \( V_{bp} \), and \( V_{cp} \)). It is the relation of the phase voltage and the amplitude of the PCC voltage (\( V_c \)). The amplitude of sensed PCC voltages is estimated as

\[
v_c = \sqrt{2 \left( V_{ap}^2 + V_{bp}^2 + V_{cp}^2 \right)/3} \tag{4}
\]

The in-phase unit templates of PCC voltages (\( u_{ap} \), \( u_{bp} \), and \( u_{cp} \)) are estimated as \[13\]

\[
u_{ap} = V_{ap}/v_1 \quad u_{bp} = V_{bp}/v_1 \quad u_{cp} = V_{cp}/v_1 \tag{5}
\]

The extracted values of \( I_{ap} \), \( I_{bp} \), and \( I_{cp} \) are passed through a sigmoid function as an activation function, and the output signals (\( Z_{ap} \), \( Z_{bp} \), and \( Z_{cp} \)) of the feed forward section are expressed as

\[
Z_{ap} = f(I_{ap}) = 1/(1 + e^{-I_{ap}}) \tag{6}
\]

\[
Z_{bp} = f(I_{bp}) = 1/(1 + e^{-I_{bp}}) \tag{7}
\]

\[
Z_{cp} = f(I_{cp}) = 1/(1 + e^{-I_{cp}}) \tag{8}
\]

The estimated values of \( Z_{ap} \), \( Z_{bp} \), and \( Z_{cp} \) are fed to a hidden layer as input signals. The three phase outputs of this layer (\( I_{ap1} \), \( I_{bp1} \), and \( I_{cp1} \)) before the activation function are expressed as

\[
I_{ap1} = w_{o1} + w_{ap}Z_{ap} + w_{bp}Z_{bp} + w_{cp}Z_{cp} \tag{9}
\]

\[
I_{bp1} = w_{o1} + w_{ap}Z_{ap} + w_{cp}Z_{cp} + w_{bp}Z_{bp} \tag{10}
\]

\[
I_{cp1} = w_{o1} + w_{ap}Z_{ap} + w_{bp}Z_{bp} + w_{cp}Z_{cp} \tag{11}
\]

Where \( w_{o1} \), \( w_{ap} \), \( w_{bp} \), and \( w_{cp} \) are the selected value of the initial weight in the hidden layer and the updated values of three phase weights using the average weighted amplitude value (\( w_o \)) of the active power current component as a feedback signal, respectively.

The updated weight of phase “a” active power current components of load current “\( w_{ap} \)" at the nth sampling instant is expressed as

\[
w_{ap}(n) = w_{ap}(n) + \mu \{ w_o(n) - w_{ap}(n) \} f(I_{ap1})Z_{ap}(n) \tag{12}
\]

Where \( w_o(n) \) and \( w_{ap}(n) \) are the average weighted value of the active power component of load currents and the updated weighted value of phase “a” at the nth sampling instant, respectively, and \( w_{ap1}(n) \) and \( Z_{ap}(n) \) are the phase “a” fundamental weighted amplitude of the active power component of the load current and the output of the feed forward section of the algorithm at the nth instant, respectively. \( f(I_{ap1}) \) and \( \mu \) are represented as the derivative of \( I_{ap1} \) components and the learning rate.

Similarly, for phase “b” and phase “c,” the updated weighted values of the active power current components of the load current are expressed as

\[
w_{bp}(n) = w_{bp}(n) + \mu \{ w_o(n) - w_{bp}(n) \} f(I_{bp1})Z_{bp}(n) \tag{13}
\]

\[
w_{cp}(n) = w_{cp}(n) + \mu \{ w_o(n) - w_{cp}(n) \} f(I_{cp1})Z_{cp}(n) \tag{14}
\]

The extracted values of \( I_{ap1} \), \( I_{bp1} \), and \( I_{cp1} \) are passed through a sigmoid function as an activation function to the estimation of the fundamental active components in terms of three phase weights \( w_{ap1} \), \( w_{bp1} \), and \( w_{cp1} \) as

\[
w_{ap1} = f(I_{ap1}) = 1/(1 + e^{-I_{ap1}}) \tag{15}
\]

\[
w_{bp1} = f(I_{bp1}) = 1/(1 + e^{-I_{bp1}}) \tag{16}
\]

\[
w_{cp1} = f(I_{cp1}) = 1/(1 + e^{-I_{cp1}}) \tag{17}
\]

The average weighted amplitude of the fundamental active power components (\( w_o \)) is estimated using the amplitude sum of three phase load active power components (\( w_{ap1} \), \( w_{bp1} \), and \( w_{cp1} \)) divided by three. It is required to realize load balancing features of DSTATCOM. Mathematically, it is expressed as

\[
w_o = (w_{ap1} + w_{bp1} + w_{cp1})/3 \tag{18}
\]

First-order low-pass filters are used to separate the low frequency components. \( \text{“}\kappa\text{”} \) denotes the scaled factor of the extracted active power components of current in the algorithm. After separating the low-frequency components and scaling to the actual value because the output of the activation function is between 0 and 1, it is represented as \( w_{I_{ap}} \). Similarly, the weighted amplitudes of the reactive power components of the load currents (\( w_{ap} \), \( w_{bp} \), and \( w_{cp} \)) of the fundamental load current are extracted as

\[
I_{I_{ap}} = w_{o1} + i_{1a}u_{ap1} + i_{2a}u_{bp1} + i_{3a}u_{cp1} \tag{19}
\]

\[
I_{I_{bp}} = w_{o1} + i_{1b}u_{ap1} + i_{2b}u_{bp1} + i_{3b}u_{cp1} \tag{20}
\]

\[
I_{I_{cp}} = w_{o1} + i_{1c}u_{ap1} + i_{2c}u_{bp1} + i_{3c}u_{cp1} \tag{21}
\]

Where \( w_o \) is the selected value of the initial weight and \( u_{ap} \), \( u_{bp} \), and \( u_{cp} \) are the quadrature components of the unit template.

The quadrature unit templates (\( u_{ap} \), \( u_{bp} \), and \( u_{cp} \)) of the phase PCC voltage are estimated using (5) as
The extracted values of $I_{aq}$, $I_{bq}$, and $I_{cq}$ are passed through a sigmoid function as an activation function to the estimation of $Z_{aq}$, $Z_{bq}$, and $Z_{cq}$.

The updated values of $Z_{aq}$, $Z_{bq}$, and $Z_{cq}$ are fed to the hidden layer as input signals. The three phase outputs of this layer ($I_{aq}$, $I_{bq}$, and $I_{cq}$) before the activation function can be represented as

\[ I_{aq} = w_{o1} + w_{aq}Z_{aq} + w_{bq}Z_{bq} + w_{cq}Z_{cq} \]

\[ I_{bq} = w_{o1} + w_{aq}Z_{aq} + w_{bq}Z_{bq} + w_{cq}Z_{cq} \]

\[ I_{cq} = w_{o1} + w_{aq}Z_{aq} + w_{bq}Z_{bq} + w_{cq}Z_{cq} \]

Where $w_{o1}$, $w_{aq}$, $w_{bq}$, and $w_{cq}$ are the selected value of the initial weight in the hidden layer and the updated three weights using the average weighted value of the reactive power components of currents ($w_{q}$) as a feedback signal, respectively.

The updated weight of the phase “a” reactive power components of load currents “$w_{aq}$” at the nth sampling instant is expressed as

\[ w_{aq}(n) = w_{aq}(n-1) + \mu \{ w_{q}(n) - w_{aq}(n) \} \Gamma(I_{aq})Z_{aq}(n) \]

Similarly, for phase “b” and phase “c,” the updated weighted values of the reactive power current components of the load current are expressed as

\[ w_{bq}(n) = w_{bq}(n) + \mu \{ w_{q}(n) - w_{bq}(n) \} \Gamma(I_{bq})Z_{bq}(n) \]

\[ w_{cq}(n) = w_{cq}(n-1) + \mu \{ w_{q}(n) - w_{cq}(n) \} \Gamma(I_{cq})Z_{cq}(n) \]

The extracted values of $I_{aq}$, $I_{bq}$, and $I_{cq}$ are passed through an activation function to the estimation of the fundamental reactive component in terms of three phase weights $w_{aq}$, $w_{bq}$, and $w_{cq}$ as

The average weight of the amplitudes of the fundamental reactive power current components ($w_{q}$) is estimated using the amplitude sum of the three phase load reactive power components of the load current ($w_{aq}$, $w_{bq}$, and $w_{cq}$) divided by three. Mathematically, it is expressed as

\[ w_{q} = (w_{aq} + w_{bq} + w_{cq})/3 \]

First-order low-pass filters are used to separate the low frequency component. “$r$” denotes the scaled factor of the extracted reactive power components in the algorithm. After separating low-frequency components and scaling to the actual value because the output of the activation function is between 0 and 1, it is represented as $w_{Lq}$.

### A. Amplitude of Active Power Current Components of Reference Source Currents

An error in the dc bus voltage is obtained after comparing the reference dc bus voltage $v_{de}$ and the sensed dc bus voltage $v_{dc}$ of a VSC, and this error at the nth sampling instant is expressed as

\[ v_{dq}(n) = v_{dc}(n) - v_{dc}(n-1) \]

This voltage error is fed to a proportional–integral (PI) controller whose output is required for maintaining the dc bus voltage of the DSTATCOM. At the nth sampling instant, the output of the PI controller is as follows

\[ v_{dq}(n) = v_{dq}(n-1) + k_p \{ v_{dq}(n) - v_{dq}(n-1) \} + k_i \int v_{dq}(n) \]

Where $k_p$ and $k_i$ are the proportional and integral gain constants of the dc bus PI controller. $v_{dq}(n)$ and $v_{dq}(n-1)$ are the dc bus voltage errors in the nth and $(n - 1)$th instant, and $w_{dq}(n)$ and $w_{dq}(n-1)$ are the amplitudes of the active power component of the fundamental reference current at the nth and $(n - 1)$th instant, respectively.

The amplitude of the active power current components of the reference source current ($w_{Aq}$) is estimated by the addition of the output of the dc bus PI controller ($w_{dq}$) and the average magnitude of the load active currents ($w_{Lpa}$) as

\[ w_{Aq} = w_{dq} + w_{Lpa} \]

### B. Amplitude of Reactive Power Components of Reference Source Currents

An error in the ac bus voltage is achieved after comparing the amplitudes of the reference ac bus voltage $v_{a}$ and the sensed ac bus voltage $v_{b}$ of a VSC. The extracted ac bus voltage error $v_t$ at the nth sampling instant is expressed as
\( v_c(n) = v_i^*(n) - v_i(n) \)

(39)

The weighted output of the ac bus PI controller \( w_{qi} \) for regulating the ac bus terminal voltage at the nth sampling instant is expressed as

\[
w_{qi}(n) = w_{qi}(n-1) + K_p \{ v_{ci}(n) - v_{ci}(n-1) \} + K_i v_{ci}(n) \tag{40}
\]

Where \( w_{qi}(n) \) is part of the reactive power component of the source current and it is renamed as \( w_{qq} \). \( K_p \) and \( K_i \) are the proportional and integral gain constants of the ac bus voltage PI controller.

The amplitude of the reactive power current components of the reference source current \( (w_{qq}) \) is calculated by subtracting the output of the voltage PI controller \( (w_{qi}) \) and the average load reactive currents \( (w_{LqA}) \) as

\[
w_{qq} = w_{qi} - w_{LqA} \tag{41}
\]

C. Estimation of Reference Source Currents and Generation of IGBT Gating Pulses:

Three phase reference source active and reactive current components are estimated using the amplitude of three phase (a, b and c) load active power current components, PCC voltage in-phase unit templates, reactive power current components, and PCC quadrature voltage unit templates as

\[
i_{aq} = w_{aq} u_{aq}, \quad i_{sb} = w_{sb} u_{sb}, \quad i_{sc} = w_{sc} u_{sc} \tag{42}
\]

\[
i_{aq} = w_{aq} u_{aq}, \quad i_{sb} = w_{sb} u_{sb}, \quad i_{sc} = w_{sc} u_{sc} \tag{43}
\]

The addition of reference active and reactive current components is known as reference source currents, and these are given as

\[
\begin{align*}
    i_a &= i_{aq} + i_{sb} + i_{sc} \\
    i_b &= i_{aq} + i_{sb} + i_{sc} \\
    i_c &= i_{aq} + i_{sb} + i_{sc}
\end{align*} \tag{44}
\]

The sensed source currents \( (i_a, i_b, i_c) \) and the reference source currents \( (i_a^*, i_b^*, i_c^*) \) are compared, and current error signals are amplified through PI current regulators; their outputs are fed to a pulse width modulation (PWM) controller to generate the gating signals for insulated-gate bipolar transistors (IGBTs) S1 to S6 of the VSC used as a DSTATCOM

V. SIMULATION AND RESULTS

A. EXISTING SYSTEM: PWM CONTROLLED DSTATCOM

This shows the Simulink modeling of DSTATCOM in which the gate signals are generated by the PWM controller. The VSC switching strategy is based on a sinusoidal PWM technique which offers simplicity and good response. Since custom power is a relatively low-power application, PWM methods offer a more flexible option which is the existing system.

VIII. CONCLUSION

A three phase VSC based DSTATCOM has been implemented for compensation of nonlinear loads using BPT control algorithm to verify its effectiveness. The proposed algorithm has been used for extraction of reference source currents to generate the switching pulses for IGBTs of VSC of DSTATCOM. Various functions of DSTATCOM such as, load balancing and harmonic elimination have been demonstrated in PFC mode with DC voltage regulation of DSTATCOM.

From simulation and implementation results, it is concluded that DSTATCOM and its control algorithm have been found suitable for compensation of nonlinear loads. These results show satisfactory performance of the BP control algorithm for harmonics elimination according to IEEE-519 guidelines in order of less than 5%. The DC bus voltage of the DSTATCOM has also been regulated to rated value without any overshoot or undershoots during load variation. Large training time in the application of complex system, selection of number of hidden layer in system is the disadvantage of this algorithm.
