Abstract. A system of two nonlinear difference-differential equations which is a mathematical model of self-regulation of glucose level in blood with time delay into consideration of insulin "age structure" is presented. The analysis carried out by qualitative and numerical methods allows us to conclude, that the mathematical model explains the functioning of the physiological system "insulin-blood glucose" in normal and pathological cases.

Key words: mathematical modeling, blood glucose level, insulin, diabetes mellitus.

1. Introduction

The self-regulation of glucose level in blood can be interpreted (Švitra, 1989; Basov and Švitra, 1998) as "predator-prey" type interaction, where the "predator" is insulin, and the "prey" is glucose. In the paper (Basov et. al., 1999) was proposed the system of two nonlinear difference-differential equations which is a mathematical model of self-regulation of glucose level in blood:

\[ \dot{I}(t) = r_I \left\{ \frac{G(t)}{K_G} + a \left[ 1 - \frac{G(t)}{K_G} \right] - \frac{I(t-h)}{K_I} \right\} I(t), \]

\[ \dot{G}(t) = r_G \left\{ 1 + b \left[ 1 - \frac{I(t)}{K_I} \right] - \frac{G(t)}{K_G} \right\} G(t). \]

Here \( I(t) \) is the level of insulin in the blood plasma at the time moment \( t \) and \( K_I \) is its mean; \( G(t) \) is the level of blood glucose and \( K_G \) is its mean; \( h \) is the time necessary for the production of insulin in \( \beta \)-cells of the pancreas; \( r_I > 0 \) characterizes the linear rate of production of insulin; \( r_G > 0 \) shows the linear growth of the level of glucose in the blood; with the help of parameters \( a \) and \( b \) a feedback is realized. Parameter \( a \) controls the rate of insulin production and parameter \( b \) regulated the level of glucose in blood.

The research shows a sufficiently good agreement between the results obtained investigating model (1)–(2) and the experimental data (Basov et. al., 1999).
From the general scheme of the blood glucose regulation (Švitra, 1989), it follows that there exists a certain “age structure” of insulin, where “younger” proinsulin by its activity yields considerably to “older” insulin. It is possible to calculate insulin “age structure” in mathematical model (1)–(2), replacing differential equation (1) by the following equation:

\[ \dot{I}(t) = r_I \left\{ \frac{G(t)}{K_G} + a \left[ 1 - \frac{G(t)}{K_G} \right] - \frac{pI(t - h) + (1 - p)I(t - h)}{K_I} \right\} I(t). \]  

In (3) \( h_p \) is the time necessary for proinsulin biosynthesis and the parameter \( p > 0 \) reflects a contribution of proinsulin fractions into a total amount of insulin produced in \( \beta \)-cells.

Investigating system (2)–(3), we assume that

\[ \frac{r_I}{K_I} = c_1, \quad \frac{r_G}{K_G} = c_2, \]

where the \( c_1 \) and \( c_2 \) are positive constant. Equations (4) mean that the resistance of the exterior of the medium is a biological constant of the organism (Kolesov, 1985).

2. Stability of Equilibrium States

2.1. Linear Analysis

The system of nonlinear differential equations (2)–(3) has the following states of equilibrium with nonnegative coordinates:

\[ \begin{align*}
    I(t) &\equiv 0, \quad G(t) \equiv 0; \\
    I(t) &\equiv 0, \quad G(t) \equiv K_G(1 + b); \\
    I(t) &\equiv K_Ia, \quad G(t) \equiv 0; \\
    I(t) &\equiv K_I, \quad G(t) \equiv K_G.
\end{align*} \]

The states of equilibrium (5)–(6) are always unstable. Below we study the stability of interior state of equilibrium (8). In the original system of differential equations (2)–(3) we make the change of variables

\[ I(t) = K_I \left[ 1 + x(t) \right], \quad G(t) = K_G \left[ 1 + y(t) \right]. \]

As a result we get the system of differential equations

\[ \begin{align*}
    \dot{x}(t) &= -\left[ r_Ipx(t - h_p) + r_I(1 - p)x(t - h) + r_I(1 - a)y(t) \right] \left[ 1 + x(t) \right], \\
    \dot{y}(t) &= r_G \left[ -bx(t) - y(t) \right] \left[ 1 + y(t) \right].
\end{align*} \]

The characteristic quasipolynomial of the linear part of system (10)–(11) is the function

\[ P(\lambda) = \left\{ \lambda + r_I \left[ pe^{-\lambda h} + (1 - p)e^{-\lambda h} \right] \right\} (\lambda + r_G) + r_Ir_Gb(1 - a). \]
The disposition of roots of (12) in the complex plane depends on values of the parameters $h_p, h, r_I, r_G, a, b$ and $p$. All they are positive according to their biological meanings (Švitra, 1989).

We study by the method of $D$-partitions (Neimark, 1948) the disposition in the complex plane of roots of the equation

$$P(\lambda; r_I, a) = 0,$$

where $P(\lambda; r_I, a)$ is quasipolynomial (12) for some fixed values of the parameters $h_p, h, r_G, b$ and $p$.

For $\lambda = 0$ from (13) we get lines $a = 1 + \frac{1}{b}$ and $r_I = 0$. Further, for $\lambda = i\sigma$ ($\sigma > 0$) we get equations in the parametric form of remaining curves of the $D$-partition on the plane $r_I a$:

$$r_I = \frac{r_G \sigma}{r_G \varphi_1(\sigma) - \sigma \varphi_2(\sigma)},$$

$$a = \frac{r_G \varphi_2(\sigma) + \sigma \varphi_1(\sigma)}{r_G b} + 1 - \frac{1}{r_I r_G b^2}$$

where

$$\varphi_1(\sigma) = p \sin \sigma h_p + (1 - p) \sin \sigma h,$$

$$\varphi_2(\sigma) = p \cos \sigma h_p + (1 - p) \cos \sigma h.$$  

As $\sigma \rightarrow 0$ from (14)–(15) we determine the so-called cups $M(r_I^M, a^M)$, whose coordinates are

$$r_I^M = \frac{r_G}{r_G \varphi_1(\sigma) - \sigma \varphi_2(\sigma)} h_p + (1 - p) h] - 1, \quad a^M = 1 + \frac{1}{b}.$$  

In the case of diabetes mellitus, for the values of parameters (Švitra, 1989)

$$h_p = 3, \quad h = 4, \quad r_G = 6.6, \quad b = 0.34, \quad p = 0.8,$$

the interesting to us part of the $D$-partition on the plane $r_I a$ is constructed on Fig. 1.

![Fig. 1. The $D$-partition on the plane of the parameters $r_I$ and $a$ in the case of diabetes mellitus.](image-url)
In the case where the normal regulation $r_G$ is sufficiently small, the parameter $b$ is sufficiently large and the values of parameters are taken as follows

$$h_p = 3, \quad h = 5, \quad r_G = 2.8, \quad b = 1.5, \quad p = 0.2,$$

the corresponding $D$-partition on the plane $r_I,a$ is presented on Fig. 2. In both the cases it is simple to show that in the domain $D_0$ all the roots of (13) have negative real parts, and passing from $D_0$ to $D_2$ acquire two complex conjugate roots of (13) with positive real parts. Thus, if the point $(r_I, a)$ is located in $D_0$, the inner equilibrium state (8) is asymptotically stable, while if the point $(r_I, a)$ goes into the domain $D_2$, in circles (8) there may appear stable periodic behavior of system (2)–(3).

### 2.2. Nonlinear Analysis

The general investigation of the nonlinear problem is rather complicated. Thus, in order to simplify the problem, we use some biological assumption. In case of diabetes mellitus $r_G$ is large, i.e., $r_G \gg r_I$. From (2) and the well known theorem of Tikhonov (Tikhonov, 1948) one gets the approximate equation

$$\frac{G(t)}{K_G} = 1 + b \left[ 1 - \frac{I(t)}{K_I} \right].$$

Then from (21) and (3) it follows

$$\dot{I}(t) = r_I \left\{ 1 + b(1 - a) \left[ 1 - \frac{I(t)}{K_I} \right] - \frac{pI(t-h_p) + (1-p)I(t-h)}{K_I} \right\} I(t).$$

After the substitution

$$I(t) = K_I [1 + x(t)]$$

we get the differential equation

$$\dot{x}(t) = -r_I [\alpha x(t) + px(t-h_p) + (1-p)x(t-h)] \left[1 + x(t)\right],$$

Fig. 2. The $D$-partition on the plane of the parameters $r_I$ and $a$ in the normal case.
where $\alpha = b(1 - a)$.

If $\alpha = p = 0$ and $r_1 = \frac{\pi}{2\pi} + \varepsilon$, the characteristic quasipolynomial of the linear part of (24) has two simple roots $\tau(\varepsilon) \pm i\sigma(\varepsilon)$, satisfying the conditions $\tau(0) = 0$, $\sigma(0) = \sigma_0 = \frac{\pi}{2\pi}$, $0 \leq \varepsilon \ll 1$ and (Švitra, 1989)

\[
\tau'_0 = \frac{2\pi}{\pi^2 + 4}, \quad \sigma'_0 = \frac{4}{\pi^2 + 4}.
\]  

(25)

All other roots of it have negative real parts. Further, let $r_1\alpha = \alpha_0\varepsilon$, $r_1\beta = \beta_0\varepsilon$. Then the characteristic quasipolynomial

\[
P(\lambda; \varepsilon) = \lambda + \alpha_0\varepsilon + \beta_0\varepsilon e^{-\lambda v} + [\sigma_0 + \varepsilon(1 - \beta_0)]e^{-\lambda v}
\]  

(26)

of the linear part of (24) has the simple roots $\eta(\varepsilon) \pm i\omega(\varepsilon)$, satisfying the conditions $\eta(0) = 0$, $\omega(0) = \sigma_0$,

\[
\eta'_0 = -\left(\tau'_0 \text{Im} P_{\varepsilon} + \sigma'_0 \text{Re} P_{\varepsilon}\right),
\]

\[
\omega'_0 = \tau'_0 \text{Re} P_{\varepsilon} - \sigma'_0 \text{Im} P_{\varepsilon},
\]

(27)

(28)

where $\eta'_0 = \eta'(\varepsilon)$, $\omega'_0 = \omega'(\varepsilon)$ at $\varepsilon = 0$, $P'_{\varepsilon} = P'_{\varepsilon}(\lambda; \varepsilon)$ at $\varepsilon = 0$, $\lambda = i\sigma_0$, and $\tau'_0$ and $\sigma'_0$ are determined by (25). From (26) it follows, that

\[
\text{Re} P'_{\varepsilon} = \alpha_0 + \beta_0 \cos \sigma_0 v, \quad \text{Im} P'_{\varepsilon} = -\left[1 - \beta_0(1 - \sin \sigma_0)\right].
\]

(29)

From the above consideration and the results of Švitra (Švitra, 1989) we conclude the following

**Theorem 1.** Let $0 < r_1 - \sigma_0 = \varepsilon \ll 1$ and let the positive variable $\eta'_0$ is determined by formula (27). Then in a sufficiently small neighborhood of zero the difference-differential equation (22) at $r_1\alpha = \alpha_0\varepsilon$, $r_1\beta = \beta_0\varepsilon$ has a unique (up to translation of time) stable periodic solution $I(t)$, for which on any segment of time of order $\varepsilon^{-1}$ one has the asymptotic representation

\[
I(t) = K_1\left[1 + \xi \cos \sigma_0 \tau + \xi^2 x_2(\tau) + O(\xi^3)\right],
\]

\[
\xi = \sqrt{\frac{\varepsilon}{b_2}}, \quad \tau = \frac{t}{1 + \varepsilon \xi^2},
\]

(30)

(31)

where

\[
x_2(t) = \frac{1}{10} \sin 2\sigma_0 \tau + \frac{1}{5} \cos 2\sigma_0 \tau,
\]

\[
c_2 = c_0 + \frac{\omega'_0 d_0}{\eta'_0 \sigma_0}, \quad b_2 = -\frac{d_0}{\eta'_0}.
\]

(32)

(33)
The characteristic quasipolynomial

\[ P(\lambda; \varepsilon) = \lambda + (r_I^0 + \varepsilon)\alpha + \alpha_0\varepsilon e^{-\lambda h} + \left[ r_I^0 + \varepsilon(1 - \alpha_0) \right] e^{-\lambda h} \]  

of the linear part of (24) in the general case has simple roots \( \eta(\varepsilon) \pm i\omega(\varepsilon) \), satisfying the conditions \( \eta(0) = 0, \omega(0) = \sigma_0 \). The following equalities hold

\[ \eta_0' = -\frac{r_I^0}{\sigma_0}(\Re P'_{0c} + \sigma_0\Im P'_{0c}), \]  
\[ \omega_0' = \frac{r_I^0}{\sigma_0}(\Re P'_{0c} - \sigma_0\Im P'_{0c}), \]  

where \( P'_{0c} = P_v(\lambda; \varepsilon) \) at \( \lambda = i\sigma_0 \) and \( \varepsilon = 0 \), \( \sigma_0 \) is the root of the equation

\[ \alpha + \cos \sigma_0 h = 0, \]  

belonging to the interval \((0, \frac{\pi}{2\hbar})\). \( r_I^0 \) is determined by the formula

\[ r_I^0 = \frac{\sigma_0}{\sin \sigma_0 h}, \]  

and \( \eta_0', \sigma_0' \) are determined by formulas

\[ \eta_0' = \frac{h\sigma_0^2}{r_I^0 \left[ h^2\sigma_0^2 + (1 + \alpha hr_I^0)^2 \right]}, \]  
\[ \sigma_0' = \frac{\sigma_0(1 + \alpha hr_I^0)}{r_I^0 \left[ h^2\sigma_0^2 + (1 + \alpha hr_I^0)^2 \right]} \]  

(Švitra, 1989). From (35) it follows that

\[ \Re P'_{0c} = \alpha_0(\alpha + \cos \sigma_0 h_p), \quad \Im P'_{0c} = -\alpha_0 \sin \sigma_0 h_p - (1 - \alpha_0) \sin \sigma_0 h. \]  

There holds the following (Švitra, 1989).

**Theorem 2.** Let \( 0 < r_I - r_I^0 = \varepsilon \ll 1 \) and let the variable \( \eta_0' \) is positive. Then differential equation (22) has for \( r_I p = \alpha_0 \varepsilon \) (up to translations of time), a unique stable
periodic solution $I(t)$, for which on any segment of time of order $\varepsilon^{-1}$ one has asymptotic representation (30), where $\sigma_0$ is determined from equation (38).

$$x_2(\tau) = A_{2s} \sin 2\sigma_0 \tau + A_{2c} \cos 2\sigma_0 \tau$$

(43)

with

$$A_{2s} = \frac{1 - 2\alpha}{2(5 - 4\alpha)} \sqrt{\frac{1 - \alpha}{1 + \alpha}}, \quad A_{2c} = \frac{1 - \alpha}{5 - 4\alpha},$$

(44)

$$\xi = \frac{t}{\sqrt{B_2}}, \quad \tau = \frac{t}{1 + C_2 \xi^2},$$

(45)

$$B_2 = \frac{\sigma_0}{\eta_0} b_2, \quad C_2 = c_2 + \frac{\sigma_0}{\sigma_0} b_2 - \frac{\omega}{\sigma_0} B_2,$$

(46)

and

$$b_2 = \frac{3hr_0^0 + 2\alpha - 1}{4h(1 + \alpha)(5 - 4\alpha)}, \quad c_2 = \frac{1 - 2\alpha}{4hr_0^0(1 + \alpha)(5 - 4\alpha)}.$$  

(47)

$\eta_0$ and $\omega_0$ are determined by (36)–(37).

3. Results of Numerical Investigation

We proceed directly to numerical investigation of the mathematical model (2)–(3) and the comparison of the obtained results with the experimental data. Here, taking into account that the resistance of exterior medium is a biological constant of the organism both in the normal and in the pathological cases, we assume the following experimental data (Švitra, 1989): $c_1 = 0.04, c_2 = 0.03$.

**Normal case.** On Fig. 3 we have constructed a numerical solution of the system (2)–(3) in case (20) for $r_I = 0.66$ and $a = 0.55$, reflecting the regulation in the system “insulin-blood glucose” of a healthy individual. On Fig. 3, also a comparison of the experimental data (Thum et. al., 1975) of the dynamics of the level of glucose in the blood of a healthy individual with the graph of the function $G(t)$ is given. It can be seen that the graph of the function $G(t)$ passes through the points of the experimental data rather well.

**Case of diabetes mellitus.** In this case the normal regulation breaks down and the time of production of insulin also shortens, due to which less potent insulin is made. The numerical solution of the system (2)–(3) in the case (19) and for $r_I = 0.6, a = 0.8$ is pictured on Fig. 4. There also, the graph of the function $G(t)$ is compared with the points of the experimental data on the dynamics of the blood glucose level of a patient with diabetes mellitus (Berger and Rodbard, 1991). It is clear, that the coincidence is rather good.

One should note that in the cases considered above the daily biorhythm of the blood glucose level is unchanged, i.e., in the course of a day we have expressions of the maximum blood glucose level.
4. Conclusions

Thus, by a synthesis of the methods of local analysis of nonlinear differential equations with retarded argument the methods of numerical investigation and as a result of certain biological considerations, we have succeeded in rather complete investigation of the mathematical model of self-regulation of glucose level in a blood taking into consideration the insulin “age structure”. The investigation made above allows us to conclude that the mathematical model (2)–(3) clarifies the functioning of the physiological system “insulin-blood glucose” rather well both in the normal and in the pathological (diabetes mellitus) cases.
