Abstract

In this work, we propose a novel approach for image categorization, which we will refer to as Bag-of-Scenes (BoS). It is based on the association of Sparse coding (Sc) and pooling techniques applied to histograms of multi-scale Local Binary Patterns (LBP) and its improved variant. This approach can be considered as a 2-layer hierarchical architecture. The first layer, encodes general local patch's structure via histograms of LBP, and the second, encodes the relationships between pre-analyzed LBP-scenes. Our method outperforms SIFT-based approaches using Sc techniques and can be trained efficiently with a simple linear SVM. Our BoS method achieves 87.02\%, 87.71\% and 79.05\% of accuracy for Scene-15, UIUC-Sport and Caltech101 datasets respectively.

1. Introduction

Image categorization consists of assigning a unique label with a generally high-level semantic value to an image. This has long been a challenging problem area in both computer vision and robotics and can mainly be viewed as belonging to the broader supervised classification framework. The difficulty of the task can be partly explained by the high-dimensional input space of the images as well as the high-level semantic visual concepts that lead to large intra-class variation.

The most common, direct framework in current vision systems is to extract directly from the images meaningful features (using shape/textures/color information) in order to achieve the maximum generalization capacity during the classification stage. Examples of such popular features in computer vision and human cognition inspired models include GIST [14] based on a bank of Gabor filters and the HOG descriptors [5].

Widely used in face recognition [21] and scene categorization [7, 16, 20], Histograms of LBP (HLBP) [13], are competitive features that achieve state-of-the-art performances in the tasks at hand. Each LBP can be considered as a non-parametric, local, visual micro-pattern texture encoding, mainly, contours and differential excitation information of the 8 neighbors surrounding a central pixel [8]. The total number of different LBPs is relatively small and by construction it is finite (from 256 up to 512). HLBP, which counts the occurrence of each LBP in the scene, can easily capture general structures in the visual scene by integrating information in a Region of Interest (ROI), while being less sensitive to local high frequency details. This property is important when the desire is to generalize visual concepts. As depicted in this work, it is advantageous to extend this analysis for several sizes of local ROIs using a spatial pyramid denoted by $\Lambda$.

Recently, the alternative scheme of Bag-of-Features (BoF) has been employed in several computer vision tasks with wide success. It offers a deeper extraction of visual concepts and improves accuracy of computer vision systems. BoF image representation [9] shares the same idea as HLBP: counting the presence (or combination) of visual patterns in the scene. BoF contains at least three modules prior to the classification stage: (i) region selection for patch extraction; (ii) codebook/dictionary generation and feature quantization; (iii) frequency histogram based image representation with spatial pyramidal matching (SPM).

In general, SIFT/HOG patches [11, 5] are employed in the first module or more recently with the efficient but computationally expensive Kernel descriptors (see [2]). These visual descriptors are then encoded, in an unsupervised manner, into a moderate sized dictionary using Vector Quantization (VQ) (see [9]). In [18], Wu and al were first to introduce LBP (via CENTRIST) into BoF...
framework coupled with histogram intersection kernel (HIK). In order to improve encoding scheme, it has been shown that local-constrained linear coding (LLC) [15], orthogonal matching pursuit (OMP) [1] or Sparse coding (Sc) [19, 7] can easily be plugged into this BoF framework as a replacement for VQ. Moreover, pooling techniques coupled with a second SPM [9] (denoted by $\overline{X}$) can be effectively used as a replacement for the global histogram based image representation.

In this paper we first re-introduce two multi-scale variants of the LBP operator coupled with a spatial pyramid $A$ analysis\(^2\) (generalizing the framework of macro-features of Boureau and al [3]). We propose the use HLBP into the $\overline{X}$ framework and call Bag-of-Sets (BoS), this new approach for scene categorization. The novel obtained feature can be trained efficiently with linear large-scale classifier. BoS can be seen as a two layer Hierarchical BoF analysis: a first fast parametric contractive low-dimension manifold encoder via HLBP and a second high-dimension sparse encoder via Sc.

2 Multi-scale Histogram of LBP

We present two existing multi-scale versions of the LBP [10] operator for an image/patch $I (n_y \times n_x)$, i.e. the C operator and its improved variant IC. Basically operator C encodes the relationship between a central block of $(s \times s)$ pixels located in $(y_c, x_c)$ with its 8 neighboring blocks, whereas IC adds a ninth bit encoding a term homogeneous to the differential excitation. Both can be considered as a parametric local texture encoder for scale $s$. In order to capture information at different scales, the range analysis $s \in S$, is typically set at $S = \{1, 2, 3, 4\}$ for this paper, where $S = \text{Card}(S)$. These 2 micro-codes are defined as follows:

\[
\begin{align*}
C(y_c, x_c, s) &= \sum_{i=0}^{7} 2^i \mathbb{1}_{\{A_i \geq A_c\}} \\
I C(y_c, x_c, s) &= \sum_{i=0}^{7} 2^i \mathbb{1}_{\{A_i \geq A_c\}} + 2^8 \mathbb{1}_{\{\sum_{i=0}^{7} A_i \geq 8 A_c\}}.
\end{align*}
\]

The different areas $\{A_i\}$ and $A_c$ in eq.(1) can be computed efficiently using the image integral technique. Efficient descriptors corresponding to the operator $op = C$ or $op = IC$, are obtained by counting occurrences of the $s^{th}$ parametric visual LBP at scale $s$ in a ROI $R \subseteq I$:

\[
h_{op}(R, x, s) = \sum_{(x, y) \in R} \mathbb{1}_{\{op(x, y, x_c, s) = j\}}.
\]

\(^2\)All ROI’s notations for the first layer will be underlined, whereas ROI’s notations for the second layer will be overlined.

The full histogram HC for $op = C$ (respectively HIC for $op = IC$), with $b = 256$ bins (512 respectively), is defined by: $h_{op}(R, s) \equiv [h_{op}(R, 0, s), \ldots, h_{op}(R, b - 1, s)]$.

2.1 HC/HIC coupled with Spatial Pyramid $A$

Instead of using image/patch $I$ as the only ROI, the entire zone can be divided into several sub-windows (possibly overlapping) via a spatial pyramid $A$ defined with $L$ layers. For each layer $l = 0, \ldots, L - 1$, $I$ is divided in $\{R_{l,v}\}$ ROI’s, with $v = 0, \ldots, V - 1$ where $V$ denotes the total number of sub-windows for the $l^{th}$ layer. A total of $V = \sum_{l=0}^{L-1} V_l$ histograms $h_{op}(R_{l,v}, s)$ are computed where $R_{l,v}$ is the $v^{th}$ sub-window of layer $l$. For each scale $s$, the vector $x(A, s)$ is obtained by the weighted concatenation of all sub-window histograms such as: $x(A, s) \equiv \{2_h h_{op}(R_{l,v}, s)\}$, where $l = 0, \ldots, L - 1$, $v = 0, \ldots, V - 1$ and $\lambda_v$ denotes the weight applied to all sub-windows of the $l^{th}$ layer.

3 Sparse Coding on HC/HIC patches

Here, we replace the collection of usual SIFT patches located in $\{O_k \subset I\}$ densely sampled on a grid over the entire image $I$ by our HC/HIC local descriptor $x(A, s)$ seen previously. Specifically, $\forall s \in S$, $F$ patches of size $(m \times m)$ associated with ROI’s $\{O_k\}$ (possibly overlapping) are extracted for $k = 0, \ldots, F - 1$. For a complete dataset containing $N$ images and $\forall s \in S$, we obtain a collection of $P = TS$ patches $X \equiv \{x_i\}, i = 1, \ldots, P$, where $T = NF$. We define by $X(s) \subseteq X$, the subset of patches $x_i$ at scale $s$ with $T$ elements.

3.1 Sparse coding overview

In order to obtain highly discriminative visual features, a common procedure consists of encoding each patch $x_i \in X(s)$ at scale $s$ through an unsupervised trained dictionary $D \equiv \{d_1, \ldots, d_K\} \subset \mathbb{R}^{d_K}$, where $K$ denotes the number of dictionary elements, and its corresponding weight vector $c_{i} \in \mathbb{R}^{K}$. In the Sc approach, in order to i) reduce the quantization error and ii) to have a more realistic representation of the patches, each vector $x_i$ is now expressed as a linear combination of a few vectors of the dictionary $D$ and not only by a single one. The problem is formulated using the following equation:

\[
\text{arg min}_{D, C} \sum_{i=1}^{T} \|x_i - Dc_i\|_2 + \beta \|c_i\|_{\ell_1} \quad s.t. \quad \|c_i\|_{\ell_1} = 1,
\]

\[\|x_i - Dc_i\|_2 + \beta \|c_i\|_{\ell_1} \quad s.t. \quad \|c_i\|_{\ell_1} = 1.\]
where the sparsity in controlled by the parameter $\beta$. The last equation is not jointly convex in $(D, C)$ and a common procedure consists of optimizing alternatively $D$ given $C$ by a block coordinate descent and then $C$ given $D$ by a LASSO procedure [12]. At the end of the process, for $\forall s \in S$, a trained dictionary $\hat{D}(s)$ is obtained.

### 3.2 Max pooling and SPM $\mathbf{\Lambda}$: HC-ScSPM/HIC-ScSPM

For an image $I$ of the dataset and given $\hat{D}(s)$ at scale $s$, $F$ sparse vectors $\{c_k(s)\}$ are computed by a LASSO algorithm [12]. An efficient descriptor $z(s) \triangleq \left[z^0(s), \ldots, z^{K-1}(s)\right] \in \mathbb{R}^F$ is obtained by the following max-pooling procedure [19, 3]:

$$z^j(s) \triangleq \max_{k \in \mathcal{D}_j} |\langle c_k^j(s) \rangle|, \quad j = 0, \ldots, K - 1, \quad (2)$$

where each element of $z(s)$ represents the max-response of the absolute value of sparse codes belonging to the ROI $\mathcal{R}_l$. In order to improve accuracy, as in section 2.1, a spatial pyramidal matching procedure helps to perform a more robust local analysis. The spatial pyramid $\mathbf{\Lambda}$ has $\mathcal{V} = \sum_{l=0}^{T-1} \sum_{v=0}^{V_l-1} \mathcal{R}_{l,v}$ with $l = 0, \ldots, T - 1$, $v = 0, \ldots, V_l - 1$. The quantity $z^j_{l,v}(s)$ for each ROI $\mathcal{R}_{l,v}$ is computed by: $z^j_{l,v}(s) \triangleq \max_{k \in \mathcal{D}_j} |\langle c_k^j(s) \rangle|$.

The final descriptor $z(\mathbf{\Lambda}) \in \mathbb{R}^F$, denoted by HC-ScSPM/HIC-ScSPM respectively, where $\hat{d} = K \mathcal{V} S$, will be defined by the weighted concatenation of all the $z^j_{l,v}(s)$ vectors: $z(\mathbf{\Lambda}) \triangleq \{z^j_{l,v}(s)\}$. $z(\mathbf{\Lambda})$ is then $\ell_2$ normalized.

### 4 Results and conclusion

We test our approach on Scene-15 [9], UIUC-Sport [7] and Caltech101 [1] datasets. We define the second layer SPM matrix $\mathbf{X}$ with $L$ levels by $\mathbf{X} \triangleq \{\mathbf{\bar{r}}_y, \mathbf{\bar{r}}_x, \mathbf{\bar{a}}_y, \mathbf{\bar{a}}_x, \mathbf{\bar{x}}\}$ of size $(L \times 5)$. For a level $l \in \{0, \ldots, L - 1\}$, the image $I$ is divided into potentially overlapping sub-windows $\mathcal{R}_{l,v}$ of size $(\mathcal{H}_l \times \mathcal{W}_l)$ and its associated weight is $\mathcal{X}_l$. In our implementation, $\mathcal{H}_l \triangleq |n_y, n_x, l|$ and $\mathcal{W}_l \triangleq |n_x, n_x, l|$ where $n_y, n_x, l$ and $l$ are the $l$th element of vectors $\mathbf{r}_y, \mathbf{r}_x$ and $\mathbf{X}$ respectively. Sub-window shifts in x-y axis are defined by integers $\mathcal{H}_y, \mathcal{H}_x \triangleq |n_y, n_x, l|$ and $\mathcal{W}_y, \mathcal{W}_x \triangleq |n_x, n_x, l|$ where $\mathbf{a}_y, \mathbf{a}_x$ and $\mathbf{a}_x$ are elements of $\mathbf{a}_y, \mathbf{a}_x$ respectively. The total number of sub-windows is equal to:

$$\mathcal{V} = \sum_{l=0}^{T-1} \sum_{v=0}^{V_l-1} \left[\frac{(1-\mathcal{H}_y)}{\mathcal{H}_y} + 1\right] \left[\frac{(1-\mathcal{W}_x)}{\mathcal{W}_x} + 1\right].$$

For the first layer intra-patch SPM matrix $\mathbf{A}$, we replace in the previous definition $n_y = n_x = m$. For all datasets, we will particularize $\mathbf{A}_1 = \left[ 1 \ 1 \ 1 \ 1 \ 1 \right]$, $\mathbf{A}_2 = \left[ 1 \ 1 \ 1 \ 1 \ 1 \right]$ and $\mathbf{A}_3 = \left[ 1 \ 1 \ 1 \ 1 \ 1 \right]$ leading to $L_1 = 1$, $V_1 = 1$, $L_2 = 2$, $V_2 = 4$, $T_1 = 2$, $V_1 = 26$ and $T_2 = 3$, $V_2 = 21$ respectively. With the particularity choice of $\mathbf{A}_2$, our framework is equivalent to macro-features of [3] whereas $\mathbf{A}_1$ represents the classic SPM approach.

For all images converted in grey color, we extract $F = s_y \times s_x = 40 \times 40$ patches $\{O_k\}$ with size $m \times m = 26 \times 26$ pixels per scale. A total of 6400 patches are extracted per image for scales $S = \{1, 2, 3, 4\}$. For sparse coding, we fixed $\beta = 0.2$. We trained models with a linear SVM via LIBLINEAR [6] ($C = 15$) with a one-vs-all multiclass approach. Accuracies are averaged over 10 cross-validation and best values of $K \in \{128, 256, 512, 1024, 2048\}$ found are noticed in the result’s tables.

### 4.1 Scene-15 dataset

We use the Scene-15 dataset containing a total of 4485 images assigned to $M = 15$ categories, with the number of images in each category ranging from 200 to 400. 100 images per class are used to train, the rest for testing. We obtained the second best re-
4.2 UIUC-Sport dataset

The UIUC-sport dataset is containing a total of 1579 images assigned to $M = 8$ categories. 60 images per class are used to train, 70 for testing. We outperform all previously published results on this dataset with 87.7% ± 1.1 of accuracy even without using macro-features through $\Lambda_2$.

4.3 Caltech101 dataset

The Caltech101 dataset is containing a total of 9144 images assigned to $M = 102$ categories. 30 images per class are used to train, the rest for testing. In [15],

Table 3. Classification rates on the Caltech101.

the 80.02% ± 0.36 of accuracy with $K = 4096$ is obtained without indicating what kind of kernel they used in LaRank solver (probably a non-linear one). Our method with 79.05% ± 0.33 of accuracy outperforms the Hierarchical CDBN approach of [17] even with a smaller dictionary size.

We have presented in this article the 2-layers BoS architecture mixing HLBp as local textures parametric encoder and Sc as non-parametric scenes encoder. Obtained performances outperform state-of-art results with a simple linear SVM. As potential future work, experimenting with LSc [7] and specialized kernels [2] will surely improve results.
