Abstract

accounts frequently get suspended. A debate over is becoming more common amongst academics, the effectiveness of suspension has arisen; an journalists important factor is that Jihadists quickly create (Chatfield, 2015; Greene, 2015; Magdy, 2015; new accounts, resurging back like the moles in Mahmood, 2012; Moriarty, 2015; Ryan, 2014; disruptive to terrorists than previously thought, ranks. whilst the bias and disruption caused to terrorism research has been underestimated.

Introduction

Jihadists have taken to social media. Twitter has emerged as their "favourite" site (Weimann, 2014) and an estimated 46,000-90,000 ISIS supporting accounts were active there in Autumn media 2014 (Berger and Morgan, 2015). Jihadists use Twitter for a variety of reasons. The first reason is to spread their messages to a wide audience. The second is for recruitment; the third is to indoctrinate further those drawn to them, like a not comprehensively) they also use Twitter for seemingly mundane conversation friends.

As a consequence of the volume of data, and its open-source nature, analysis of this source of Jihadists are very active on Twitter but their intelligence about terrorist and extremist activity and government practitioners the "whack-a-mole" game. This causes biases for Stern and Berger, 2015). Whilst there is very terrorism and intelligence analysts. Whilst detailed research on the Twitter structure and widely acknowledged, little research investigates strategies of the top-down, officially-controlled the problem. In this study we identify resurging tiers of Jihadist terrorist groups (Stern and Jihadist accounts with novel methods, and Berger, 2015), we argue that the field could provide detailed analysis going beyond previous benefit from more sustained research on the case-studies. We show that suspension is less larger, bottom-up community of Jihadist massed

Another consequence of how numerous and vocal Jihadists are on Twitter, is the political, cultural and media pressure to take down - or suspend – terrorism supporting accounts (Levy, 2014; Moriarty, 2015). In recent years this has led to several changes in Twitter's suspension policy, and an enormous increase in the number of suspensions. A debate has now arisen in the academic and literature effectiveness of these suspensions (Arthur, 2014; Fisher, 2015; Gladstone, 2015; Stern and Berger, 2015). The assumption is that suspending terrorist supporting accounts reduces the number of terrorists on Twitter. It is assumed that this, in crucible of radicalisation. And finally, (although turn, will help counter the objectives for which Jihadists are using social media in the first place: amongst recruitment, radicalisation, spreading propaganda and threats. On the other side of the freedom of speech, and how realistically and provide these estimates. achievable the number of suspensions needed to make a dent in the problem is.

problematic phenomenon associated Berger, 2015). This phenomenon 2014; Stern and Berger, 2015). Those who create resurgent. these resurging whack-a-mole accounts we call Stern and Berger (2015) conducted a case study definition later in the paper.

challenge for those performing the suspensions. gathering. One of their claims is that finding Their quantity makes identification difficult and matching resurgent accounts, and analysing them so they often go unnoticed. The impact of as continuations of the same account is easy. researchers being unable to identify or control Furthermore, they claimed the "suspension had for resurgents is that their datasets will suffer cost nothing in intelligence value... and the new biases; the main bias being replicate error. If the account continued the stream of press releases". dataset contains duplicate resurgent accounts Whilst this may be true for researchers tracking a who get treated as independent data points, this particular case study account, especially official clearly causes errors in any research addressing a media accounts, any researcher analysing the range of issues: the number of Jihadist accounts, Jihadist massed ranks on Twitter is going to the level of support for a particular course of struggle. We suggest that trying to identify all action, how unusual a particular behaviour is, corresponding resurgent accounts in a dataset of and so on.

Berger and Morgan's estimate of the (carefully another one of our aims in this paper. worded) number of "ISIS-supporting Twitter accounts". The problem is that we do not know Stern and Berger also determined the rate at manv unique **ISIS** supporters represented by these accounts. In another followers and calculated that it would take example, Twitter claimed that it had suspended months or years to regain all their followers. (Gladstone, 2015). Again, it is unknown how numeric costs" since ISIS supporters must many ISIS supporters this represents. These "reconstruct their social networks and reestablish problems occur because there are no methods to trust" (Stern and Berger, 2015). While there may identify resurgent accounts amongst this volume be costs for some suspended accounts, this of data, or control for the biases that they cause, picture is incomplete. We hypothesise that

debate are concerns over loss of intelligence, One of our aims is to help develop such methods

It is clear that resurgents cause problems for suspension and for research, yet academic study Central to this debate is another significant and of them is lacking. Previous studies have with discussed suspension and resurgence as a Jihadist social media research: "many of those potential flaw with the generalisability of their suspended users simply sat down at their findings (Berger and Morgan, 2015; Chatfield, computers the very next day, created new 2015; Magdy, 2015). However, almost no accounts, and started all over again" (Stern and research has been done to characterise and is describe suspended or resurgent accounts – acknowledged in a range of studies (Chatfield, partly due to the lack of methods for finding 2015; Magdy, 2015; Berger and Morgan, 2015) them. The impact of resurgents on the and widely referred to as "whack-a-mole" effectiveness debate, therefore, currently rests on (Arthur, 2014; Berger and Morgan, 2015; Levy, Stern and Berger's (2015) case study of a single

"resurgents" and we provide a more detailed of the suspension and single resurgence of the official al Shabaab Twitter account in January 2013 and concluded that suspension is disruptive Resurgents do not just cause a whack-a-mole to terrorists but not to research or intelligence 46,000-90,000 accounts is so time-consuming for humans that there is likely to be an An example of a problem caused by resurgents is intelligence cost. Addressing this hypothesis is

are which their resurgent case-study account accrued 10,000 ISIS linked accounts in a single day They then argued that suspension imposes "clear repeatedly) built their reputation and the trust of research datasets. On the other hand we do the community, when they return as resurgents, exclude those who are consciously masquerading the nature of Twitter means that they can quickly as different people (e.g. operating multiple seek out close comrades from their previous personas or a variety of automatic bots) and we network, initiate contact and re-establish their consider the implications of this in the credentials. Therefore we predict that the number discussion. of followers of resurgent accounts should grow faster than naturally growing Jihadist accounts In this paper we aim to find sets of accounts who must establish credentials from scratch belonging to the same resurgents. Once we have rather than simply renew them.

accelerated growth resurgents. One relevant Twitter phenomenon accounts, as well as looking at Follow-Friday as could be "Follow Friday" (Leavitt, 2014), where a possible driving mechanism. We will also participating users recommend accounts (on provide an estimate of the proportion of Jihadist Fridays) to their followers. These tweets are accounts which are just duplicates and the often signposted with the hashtags "#ff" or proportion which represent unique Jihadists. "#followfriday", "#ff e.g. @randomuser1 @twitteruser123". hypothesise that they could be helping to drive distribution of Jihadists on social media, as well growth, and will perform an initial test of how as an appreciation of how disruptive suspension common they are to assess the viability of this.

resurging from suspension is a significant challenging, in the process, enough feature of modern terrorism to merit conclusions further study and definition. With currently only behaviour drawn by others. a single case study, we suggest that the next logical step is to study more resurgents, and this is the main aim of our paper. However, since the Methods world of modern terrorist activity is one of social media and big data, conclusions drawn about case studies cannot be appropriately generalised to the whole population of Jihadists. We therefore, as has been identified as necessary in the study of Twitter Jihadists in general, propose using big data methods (Berger and Morgan, 2015) on a large sample of resurgents.

We define a Twitter resurgent as any user who has created multiple accounts on Twitter under different handles (unique user-names beginning '@'). Resurgence does not only occur as the their suspension by changing their handle or multiple backup accounts.

because Jihadist accounts have previously (and however, as they cause the same biases to

done that, we can study and describe them. We assess how disrupted they We will also consider other factors that could quantitatively analysing the rate at which they amongst accrue followers compared to non-resurgent #followfriday These findings will give terrorism researchers a We better understanding of the true numbers and is for research. We therefore set out the first large scale description of resurgent Jihadists, a We think that the phenomenon of accounts significant phenomenon in modern terrorism, some about Jihadist social media

1. Dataset

The sampling algorithm used was developed to bias sampling toward accounts that tended to have numerous links to other accounts that had already been sampled. The reason for doing this was the principle of homophily: the tendency of people to associate with others similar to them (McPherson, 2001). This principle has been shown to lead to highly intra-linked communities on Twitter that bias their interactions to other members of the community and share a social direct result of suspension; some users pre-empt identity (Bryden, 2011; 2013; Tamburrini, 2015). Consequently, we reasoned that Jihadists would All bias the accounts that they followed towards resurgent types are included in the definition, other Jihadist accounts and set up our sampling algorithm accordingly.

(Goodman, 1961) to identify Jihadist Twitter Jihadist massed ranks. accounts. This approach enabled us to grow the sample, whilst weighting sampling towards During sampling, some accounts were protected, accounts with numerous links to accounts suspended or had voluntarily changed their useralready identified. A handful of publicly-known, name. We moved these to an "inactive sample" official "media" Jihadist Twitter accounts named where we recorded all the account information, by newspapers provided our starting point. We but they no longer contributed to the 10% then manually inspected the Twitter followers of threshold check. We identified suspended users these accounts, aided by Twitter's "Who to by the official suspension report with which follow" algorithm, and from our analysis we Twitter had replaced their pages. Protected users identified 34 'unofficial-but-supporting', Jihadist had activated privacy settings accounts. For practicality, we selected only biography, pictures and summary meta-data were English speaking accounts. We then used this available. Non-existent accounts display an starting sample to seed the snowball algorithm.

July 2015 (77 days, with power issues preventing their non-existence, since Twitter does not report sampling on 10 days). On each day we looked at them as suspended we assume that the users all accounts followed by those already in our changed their handles themselves. sample. We then sampled any account identified as being followed by >10% of the users in our sample, and with <1,000 followers of its own.

accounts in our sample). We switched to the 10% accounts, identifying and classifying resurgents. threshold once we had sampled 100 accounts.

The upper limit of 1,000 followers was selected *resurgent* for two reasons. Firstly, to prevent the inclusion of popular journalists and academics who are When comparing accounts, we used open criteria connected outwards to followers. Such community transcending identical journalists were liable to divert the sampling biography or location was necessary to direct our dataset away from the official, top- "@jihad bob2" and "@jihad bob3".

down Jihadist media accounts covered in other We therefore used weighted snowball sampling research, and towards the largely neglected

official Twitter message that the user cannot be found (despite our evidence that they previously We snowball sampled daily between May and did). Although no information is provided about

2. Finding resurgent Jihadists

To identify resurgent accounts we used a We selected the 10% threshold to grow the quantitative approach that helped draw our sample slowly, without accelerating, whilst attention to accounts whose Twitter biographies, remaining within a relatively tight community of names and locations contained at least 30% of English speaking Jihadists (the principle of the same words We set out the rationale for why homophily). While our sample was smaller than our quantitative approach in needed, over human 100 users we used a fixed threshold (new identification of accounts, in Supplementary accounts must be followed by more than 10 Material 1. We then visually assessed those

Defining a set of accounts belonging to a

often both highly interlinked with the networks, for determining whether they formed a set. non-Jihadist However, in practically all cases, an almost match between handle. name. away from the Jihadist community. Our cut-off is sufficient. Biography and handle were the similar to, although more ruthless than, the strongest indicators, whilst location, surprisingly, precedent set by Berger and Morgan (2015) who was still informative due to peoples' unique used a 50,000 cut-off, finding that accounts more spelling, punctuation, and choice of descriptive popular than this were unrelated. Secondly, by terms. A hypothetical, illustrative example of an avoiding the more 'popular' accounts, we aimed almost identical match would be the handles

Figure 1. An illustrative example from our data of two resurgent accounts which we classified as a set. They have almost identical handles and almost identical biographies. Their images were not inspected, but their profile images are an almost identical match too. Screenshots of two user accounts taken from http://twitter.com.

Figure 2. An illustrative example from our data of two accounts which we did not classify as duplicates of one another, despite some similarities. Screenshots of two user accounts taken from http://twitter.com.

3. Do resurgents accrue followers faster?

investigated how disrupted resurgent accounts are by calculating their rate of follower accrual versus non-resurgent controls. As we Results were unable to find other matching resurgents, we treated all those who had not been identified as non-resurgent controls. We calculated growth rate by dividing the number of followers an account had upon sampling by the number of days between creation and sampling. We used the non-parametric Mann-Whitney U test after

ruling out normality (both p = 0.00, 2.d.p, Kolmogorov-Smirnov).

We sampled 1,920 English speaking Jihadist accounts from Twitter. By the end of sampling 1,080 had been suspended, 141 accounts were private, 97 no longer existed and 602 were active (figure 3). Only 1,858 of the users had sufficient

name, location and biography information for analysis.

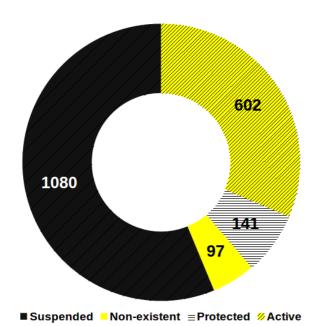

Figure 3. The distribution of our dataset of 1,920 English speaking Jihadist Twitter accounts. By the end of sampling, 1,080 had been suspended by Twitter, 141 had set their accounts to private, 97 no longer existed due to voluntary name change and 602 were still active.

1. Terrorist group affiliations

The majority of accounts do not declare a terrorist organisation affiliation, nor does a simple content analysis allow for unequivocal categorisation. Amongst 300 randomly selected users, 39 (13%) provided an allegiance, of which all gave ISIS, IS, Islamic Caliphate, Baqiya or Khilifa. Amongst the 261 that didn't, 34 (13%) gave one of the four most common locations: "Dar ul Kufr" [Land of the unbelievers] (n=16, 6%), "UK" (n=12, 5%), "Dunya" [the nonspiritual, temporal world] (n=3, 1%), and "Somalia" (n=3, 1%); with the sharing of extremist content and pro-Caliphate sentiment also common. Twitter also suspended 56.3% of our sample, evidence that suggests they were engaging in extremist activity. We therefore categorise our sample as Jihadists, whilst assuming, based on location and content, that the majority are ISIS-supporting members of the "Baqiya family" (Amarasingam, 2015).

2. Finding resurgent Jihadists

Using the quantitative approach outlined in the methods, we estimated the number of unique Jihadist users by identifying resurgents: users in the dataset who had multiple, matching replicate accounts.

From 1,858 user accounts with information to analyse, only 1,484 (79.9%) were unique Jihadists. The remainder, over one in five accounts, were duplicates: resurgent accounts. 192 (12.9%) of the unique users were resurgents who owned, on average, 2.95 accounts (a set of mean size 2.95) within the three month period (table 1).

The other statistic commonly reported is the number of Jihadist accounts that have been taken down or suspended. This also overestimates the number of unique Jihadists. Performing the same analysis with the suspended users with information to analyse (n=1,066), we found only 757 (71.0%) unique Jihadists. 114 (10.7%) of these unique users were resurgents, owning a mean of 3.71 suspended resurgent accounts in three months (table 1).

	Entire Sample	Suspended Users
Accounts analysed	1,858	1,066
Unique Jihadists	1,484 (79.9%)	757 (71.0%)
Duplicate accounts	374 (20.1%)	309 (29.0%)
Unique users who were resurgents	192 (12.9%)	114 (10.7%)
Mean # of accounts belonging to each resurgent	2.95	3.71

Table 1. Identification and quantification of resurgents in the dataset: users who had multiple, matching replicate accounts.

3. Resurgents accrue followers faster

We found that the growth rate of resurgent once, 1-tailed Mann-Whitney U) than that of naturally suspension. non-resurgent accounts (n=1.292. growing, median 8.37) (figure 4).

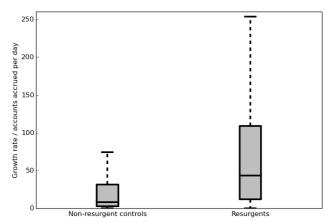

Figure 4. The growth rates (followers accrued per day) of resurgent accounts (n=566) versus naturally growing Jihadist accounts (n=1,292). The plot shows the growth rate of resurgent accounts is significantly higher than that of nonresuraent accounts.

4. Jihadist Follow-Friday

Having shown that resurgent accounts grow faster than those of non-resurgents, we searched for explanatory factors. We observed a similar phenomenon to "Follow-Friday" within the Jihadist Twitter community and assessed their viability as a growth driving mechanism by testing how common these tweets were.

Downloading the entire daily tweet output of our sample generated a corpus of approximately 155,000 tweets. We randomly-selected 2,500 tweets from this corpus; 46 (1.84%) fitted the Jihadist Follow-Friday structure.

Although we dub them "Jihadist Follow-Friday" tweets, zero (0.0%) contained Friday hashtags. Furthermore, none (0.0%) of the 46 examples promoted more than one user per tweet, with 17 (37.0%) repeating the name several times per "Follow: @jihadistaccount123 e.g.

@jihadistaccount123", @jihadistaccount123 and the remaining 29 (63.0%) naming them only **SUPPORT** "FOLLOW e.g. & accounts (n=566, median 43.8) is significantly @jihadistaccount123". Three tweets (6.52%) greater (p < 0.0001 [exact p-value < 2.38×10^{-40}], also stated that the user had returned from

> As an indicator of whether Jihadist Followtweets are significant enough contribute to re-growth, this result estimates that there are 2,852 tweets (1.84%) promoting other Jihadist accounts in our dataset of 155,000 tweets.

Discussion

Suspension and resurgence are significant phenomena in modern, online terrorism. As resurgents are difficult to find in large numbers, research into them is scarce, relying on Stern and Berger's (2015) case study alone. Furthermore, terrorism research treats the duplicate resurgents as independent data points, biasing social media research into the numbers, opinions behaviour of Jihadists. We found resurgents, estimating that within our sample only 79.9% of Jihadist Twitter accounts belong to unique Jihadists, with a lower 71.0% of unique Jihadists amongst suspended accounts. This researchers a better picture of the patterns displayed by resurgents, as well as a scale of the significant biases for research and estimates and the continuous disruption intelligence to gathering.

With the identification of resurgents comes the ability to analyse them beyond individual case studies. Previous work has concluded that there are "clear numeric costs" to resurgents who suffer slow regrowth as a cost of suspension (Stern and Berger, 2015), contrary to this single al-Shabaab account however, we have shown that in our sample resurgents grow significantly faster (median 43.8 accounts accrued per day) than non-resurgent Jihadists (median 8.37). Whilst it remains possible that this might not be sustained long enough to get back all of their old followers, especially the curious Westerners,

help to drive this accelerated growth also merits on Twitter. We categorised our sample as prodiscussion topics.

46,000-90,000. However, we have shown that an (2015) reported, headline-catching statistic is the limited by snowball sampling's bias towards the number of ISIS accounts suspended; Twitter seed list, after sampling 1,920 accounts from a reported suspending 10,000 accounts. However, seed list of 34, any initial bias should have been supporters. We suggest that while the rate of the ability of our study to make statements about even when suspensions escalate, the principle popularity to exclude bots. behind our finding remains crucial. All of these results highlight the dangers in working with a A potential critique of our sampling method Jihadist dataset without correcting it for (continually looking for new accounts) is that it resurgents.

of resurgents is the contribution to the reaching out to newly discovered accounts that suspension effectiveness debate. A great deal of need not be new to Twitter. We would also point political and public pressure exists to suspend out that although snowball sampling cannot terrorists and their supporters from social media reach disjoint groups, such a hypothetical, sites. Although intelligence concerns often take unconnected terrorist group is by definition "a distant third" place to business and cultural unrepresentative of the ISIS-dominated Twitter concerns, some argue that the intelligence costs environment. We do, however, suggest that the themselves are limited (Stern and Berger, 2015). best course of action is for researchers Whilst our results do not address the cultural or themselves arguments, suspensions are less disruptive to terrorists than also excludes those masquerading as bots or previously argued; furthermore, suspensions multiple personas. These are phenomenon cause significant biases to data and its analysis. potentially causing additional replicate biases to Rather than leading us, however, to advocate terrorism research and therefore merit further against suspension – there are convincing ethical research. and intelligence quality improving arguments (Stern and Berger, 2015) - we propose using Although there appear to be some statistical methods to control for it.

there is no obvious disruption to Twitter when We consider our dataset of accounts, and their considered as a crucible of radicalisation, suspension rates, to be generalisable to the Whether or not Jihadist Follow-Friday tweets unofficial, English-speaking, Jihadist community further study, as they seem prominent (1.84% of ISIS members of the "Baqiya family" (the tweets) given the number of alternative friendly network of online ISIS supporters) (Amarasingam, 2015), although terrorist group affiliation is almost impossible to assess without Our findings could help analysts to put reported additional sources of data. It is, however, in line numbers and statistics in a more appropriate with the political dominance of ISIS during context. Berger and Morgan estimated the summer 2015, the nature of the "Baqiya family" number of ISIS supporting Twitter accounts at (Amarasingam, 2015), and Berger and Morgan's estimate of 46,000-90,000 improved estimate should drop below 36,800- supporting accounts during a similar length time. 72,000 (79.9%) unique users. Another commonly Although it is possible that generalisability is our results suggest that this should be corrected diluted. We therefore associate our results only to represent only 7,100 (71.0%) unique ISIS with the general "Jihadist" community, limiting suspensions remains stable, our specific results differences between specific terrorist groups. of 79.9% (overall) and 71.0% (amongst Inspection of the data does, however, indicate suspended) may have some usefulness, but that success in our aim of using a minimum

could be biased towards resurgents. We defend the appropriateness of our sampling, however, as One of the implications of this improved picture it will still snowball into a wider community, to analyse their dataset they do suggest that resurgents. Finally, our definition of resurgents

issues with generalising our findings directly to

may be highly informative. Again, these sampling methods differ from study to study. challenges only emphasise the importance of researchers attempting to find resurgents in their data for themselves.

Our study included several types of resurgents, This including backup accounts and those created methodological approaches towards the study of after suspension. The difference between a resurgent Jihadists. The new methods give us backup and post-suspension account is not a novel insights into the proportion of fastbinary classification but a spectrum, depending growing, duplicate accounts (20-30%), which in on whether the main account has been turn suggest some crucial new approaches in suspended, the age of the backup before and terrorism studies: adjusting numerical estimates, since becoming the main account, and the ratio between these. Recording data to investigate to identify and control for the significant number these is therefore beyond the scope of this of resurgents. Our quantitative method in article, but merits a future study. Crucially particular, which we hope to calibrate further in however, a lower rate for backups would lower future work, appeared very useful for quickly the rate for combined resurgents, and this thus finding resurgents, and this presents a clear indicates the robustness of our significantly example of the wider importance and power of elevated result.

Limitations

A limitation of our "Jihadist" study is that we cannot make statements about the differences between specific terrorist groups. These findings could also benefit from more work with a

Berger and Morgan's work, there are several broader sampling procedure, as there are limits possible counter-explanations. Scaling by 79.9% on generalising our sample to the unofficial, predicts that over 20% of their users have English-speaking, Jihadist, Twitter community resurged back, but they only reported ~7.5% (snowball sampling methods both limit the being suspended in the first place. There are ability to reach disjoint groups, and exhibit bias however, three reasons why this need not towards their seed lists). Additionally, our contradict our findings, nor stop us applying our estimates are conservative upper bounds as we result to their data. Firstly, they acknowledge could have missed some resurgents due to the that the suspension rate has dramatically challenge of finding resurgents amongst big data. escalated since, and in our data it was 56.3%. Our estimates are also upper bounds as our Secondly, name-changing and backup accounts definition excluded those masquerading as bots sources of resurgents and are or multiple personas, and our study amalgamated presumably not covered under their reported several types of resurgents, including backup suspension statistics. Finally, it appears that their accounts and those created after suspension. sample was not continuously re-checked for Although there are likely to be differences suspensions. Thus their suspension rate may between backup and post-suspension resurgent actually be higher than reported. In the specific accounts (we hypothesise that their longer case of our Twitter example, where all the lifespan and insignificance to followers would accounts were active during a single day, our give backup resurgents a lower growth rate), findings may also not be applicable. However, testing this is non-trivial. There may also be whenever accounts are reported suspended over limitations with generalising our findings a period greater than several weeks, our findings directly to all other numerical estimates, as

Conclusion

paper marks step change recognising dataset biases, and seeking methods using quantitative analysis to investigate a range of terrorism behaviours.

Why a quantitative approach?

1,920 users for replicates would be very time attributes had sufficient information to analyse. consuming. Berger's sample of 46,000+ would make the task close to impossible. The feasibility of this task is partly limited by its reliance on human memory capacity. Whilst working memory capacity is a mere 7±2 items (Miller, 1956), we suggest that a more appropriate indicator is recognition memory - the ability to recognise whether or not something matching the account had been encountered earlier in the dataset. Standing (1973) empirically derived equations showing that recognition memory follows a power law with the number of items presented. We can therefore calculate that if humans inspected our 1,920 accounts as printed words, Standing's work predicts the number capable of being held in memory is: $10^{((0.92*log(1,920 items))-0.01)} = 1,025$

Since for many accounts we also have a screenshot of their Twitter profile, Standing's equation for pictorially presented data predicts: $10^{(0.93*log(1,920 items))+0.08)} = 1,360$

The upper limit of human memory whilst attempting a match search with our medium sized dataset is therefore ~53-71% of previously encountered accounts. Since each account is actually represented by around 10 words, not oversimplification generates this conservative extremely upper limit. Recalculating for Berger's conservative estimate of 46,000 ISIS accounts, only ~41-56% can be held in recognition memory; another overestimation. Standing's results may also not generalise this far beyond the 10,000 items used in his work.

To aid the quick finding of resurgent accounts, we therefore used a quantitative approach to draw our attention to several accounts at a time. Hypothetically, the simplest approach might have been selecting two random accounts to evaluate simultaneously. This would have been ineffective. A quantitative approach should work

on an assumption or hypothesis about the data. We assumed that finding matches would be aided by selecting accounts whose biographies, names and locations contained >30% of the same Manually inspecting the complete dataset of words. This meant that only accounts with these
