

## Isolated complete bitemporal hemianopia in traumatic chiasmal syndrome

Dai Woo Kim<sup>1</sup>, Ungsoo Samuel Kim<sup>1,2</sup>

A 29-year-old man presented with a chief complaint of lateral blindness in the left eye at 4 months after an accidental fall. His best corrected visual acuity was 0.7 in the left eye and 1.0 in the right eye. Visual field test showed a complete bitemporal hemianopic defect without any neurologic symptoms. An orbital computed tomography scan with non-enhancement conducted at the time of the visit showed multiple frontal skull fractures and cerebromalacia a small fracture in the sphenoidal bone both frontal lobes. No radiological abnormalities of the visual pathway were detected. Optical coherence showed reduced thickness in the retinal nerve fiber layer, primarily in the superior and inferior part of the left eye. To our knowledge, a complete bitemporal hemianopia without neurological deficits is extremely rare in traumatic chiasmal syndrome.

Quick Response Code:

A 29-year-old man sustained a closed head trauma in an accidental fall. Four months after the accident, he presented with a chief complaint of lateral blindness in the left eye. His best corrected visual acuity was 0.7 in the left eye and 1.0 in the right eye. Humphrey visual field test showed a complete bitemporal hemianopic defect [Fig. 1]. Other than the visual defect, no focal neurological deficits, including cranial nerve palsy, diabetes insipidus, cerebrospinal fluid rhinorrhea, and panhypopituitarism were detected. Fundus photography showed a pale disc in the left eye [Fig. 2a]. An orbital computed tomography scan with nonenhancement conducted at the time of the visit showed multiple frontal skull fractures and cerebromalacia in both frontal lobes. No radiological abnormalities of the visual pathway were detected. Optical coherence tomography (OCT) showed reduced thickness in the retinal nerve fiber layer (RNFL), primarily in the superior and inferior part of the left eye [Fig. 2b].

### Discussion

Chiasmal syndrome comprises various signs and symptoms associated with lesions of the optic chiasm. Trauma is one of the rare etiologies of chiasmal syndrome because few patients survive after the severe impact.<sup>[1,2]</sup> Various visual field defects including bitemporal hemianopia, temporal hemianopia, and quadrantanopia have been reported;<sup>[2]</sup> however, complete bitemporal hemianopia without profound visual loss, as seen in the present case, is rare. Frequently associated neurological complications include cranial nerve palsies, diabetes insipidus, cerebrospinal fluid rhinorrhea, panhypopituitarism, and

**Figure 1:** Humphrey automated static perimetry shows complete bitemporal hemianopia

carotid-cavernous fistula.<sup>[2-4]</sup> However, in our patient, visual deficit occurred in isolation without other neurological abnormalities at 7 months' follow-up after the injury. In our case, the RNFL loss was detected primarily in the superior and inferior regions in OCT with 4-quadrant or 1230° segment views. The reason that the OCT findings of the traumatic bitemporal hemianopsia did not show the classical bow-tie pattern may be attributed to the complex nature of the traumatic injury.
