**Speeding it up**

Brute force ray tracing is really slow!

Consider rendering a single image with:

- $m \times m$ pixels
- $n$ primitives
- average ray path length of $d$
- $\ell$ shadow ray per intersection
- 0, 1, or 2 rays cast recursively per intersection

Asymptotic # of intersection tests $\approx O(m^2 \cdot n \cdot 2^d \cdot \ell)$

For $m=1,000$, $n = 1,000,000$, $\ell = 10$, $d = 10$…very expensive!!

In practice, some acceleration technique is almost always used.

We’ve already looked at reducing $d$ with adaptive (early) ray termination.

Now we look at reducing the effect of $n$ (number of primitives)…
Faster ray-polyhedron intersection

Let’s say you were intersecting a ray with a triangle mesh:

Straightforward method

- intersect the ray with each triangle
- return the intersection with the smallest $t$-value.

Q: How might you speed this up?

bbox
Hierarchical bounding volumes

We can generalize the idea of bounding volume acceleration with hierarchical bounding volumes.

Key: build balanced trees with tight bounding volumes.
Uniform spatial subdivision

Another approach is **uniform spatial subdivision**.

**Idea:**
- Partition space into cells (voxels)
- Associate each primitive with the cells it overlaps
- Trace ray through voxel array using fast incremental arithmetic to step from cell to cell

**Q:** Given a $10^6$ triangle football stadium with a $10^6$ triangle teapot on one of the seats, would a single uniform spatial subdivision be a good idea?
Non-uniform spatial subdivision: Octrees

Still another approach is non-uniform spatial subdivision.

One of these is quadtrees / octrees:
Non-uniform spatial subdivision: $k$-d trees

Another non-uniform subdivision is $k$-d ($k$–dimensional) trees:

If the planes can be non-axis aligned, then you get BSP (binary space partitioning) trees.

Various combinations of these ray intersections techniques are also possible.

Aliasing

Ray tracing is a form of sampling and can suffer from annoying visual artifacts...

Consider a continuous function $f(x)$. Now sample it at intervals $\Delta$ to give $f[i] = \text{quantize}[f(i\Delta)]$.

Q: How well does $f[i]$ approximate $f(x)$?

Consider sampling a sinusoid:

In this case, the sinusoid is reasonably well approximated by the samples.
Aliasing (con’t)

Now consider sampling a higher frequency sinusoid

We get the exact same samples, so we seem to be approximating the first lower frequency sinusoid again.

We say that, after sampling, the higher frequency sinusoid has taken on a new “alias”, i.e., changed its identity to be a lower frequency sinusoid.
Aliasing in rendering

One of the most common rendering artifacts is the “jaggies”. Consider rendering a white polygon against a black background:

![Aliasing in rendering](image)

We would instead like to get a smoother transition:

![Aliasing in rendering](image)
Antialiasing

**Q:** How do we avoid aliasing artifacts?

1. **Sampling:** more samples ... better display
2. **Pre-filtering:** analytic integration
3. **Combination:** supersampling + averaging down

Example - polygon:
Polygon anti-aliasing

Without antialiasing

With antialiasing

Magnification
Antialiasing in a ray tracer

We would like to compute the average intensity in the neighborhood of each pixel.

When casting one ray per pixel, we are likely to have aliasing artifacts.

To improve matters, we can cast more than one ray per pixel and average the result.

A.k.a., super-sampling and averaging down.
Antialiasing by adaptive sampling

Casting many rays per pixel can be costly. We need another acceleration trick!

If there are no rapid changes in intensity at the pixel, maybe only a few samples are needed.

Solution: adaptive sampling.

Q: When do we decide to cast more rays in a particular area?
Temporal aliasing

Suppose we are rendering a “clock” with a fast turning hand:

What happens if we sample too infrequently? (This is sometimes called the “wagon wheel” effect.)

Another more common scenario is something moving quickly across the frame, e.g., a fast-moving particle:

How might we address these temporal aliasing effects?
Motion blur

By averaging consecutive frames together within an exposure interval, we get motion blur:
