## Abstract

The room temperature reaction of  $C_6F_6$  or  $C_6F_5H$  with  $[Ru(IEt_2Me_2)_2(PPh_3)_2H_2]$  (**1**;  $IEt_2Me_2 = 1,3$ -diethyl-4,5-dimethylimidazol-2-ylidene) generated a mixture of the *trans*-hydride fluoride complex  $[Ru(IEt_2Me_2)_2(PPh_3)_2HF]$  (**2**) and the bis-carbene pentafluorophenyl species  $[Ru(IEt_2Me_2)_2(PPh_3)(C_6F_5)H]$  (**3**). The formation of **3** resulted from C-H activation of  $C_6F_5H$  (formed from  $C_6F_6$  via stoichiometric hydrodefluorination), a process which could be reversed by working under 4 atm  $H_2$ . Upon heating **1** with  $C_6F_5H$ , the bis-phosphine derivative  $[Ru(IEt_2Me_2)(PPh_3)_2(C_6F_5)H]$  (**4**) was isolated. A more efficient route to **2** involved treatment of **1** with 0.33 eq of TREAT-HF ( $Et_3N \cdot 3HF$ ); excess reagent gave instead the  $[H_2F_3]^-$  salt (**5**) of the known cation  $[Ru(IEt_2Me_2)_2(PPh_3)_2H]^+$ . Under catalytic conditions, **1** proved to be an active precursor for hydrodefluorination, converting  $C_6F_6$  to a mixture of tri, di and monofluorobenzenes (TON = 37) at 363 K with 10 mol% **1** and  $Et_3SiH$  as the reductant.

## Introduction

Recent years have witnessed increasing evidence for the valuable role of N-heterocyclic carbenes (NHCs) and their derivatives in catalytic transformations involving organofluorine substrates.<sup>1</sup> Thus, organocarbene catalysts have been employed for the formation of both C-F and C-CF<sub>3</sub> bonds,<sup>2,3</sup> as well as enantioselective transformations of fluorine containing substrates.<sup>4</sup> Transition metal NHC complexes have also been employed for C-F bond formation through hydrofluorination,<sup>5-7</sup> but have perhaps received more attention in processes in which C-F bonds are broken (Scheme 1), either through cross-coupling<sup>8</sup> or, of particular relevance to the work reported in this manuscript, hydrodefluorination (HDF).<sup>9-11</sup>

**Scheme 1**

Prompted by our studies over a number of years on catalytic HDF of fluoroaromatic substrates using ruthenium NHC hydride precursors and the elucidation by DFT calculations of a mechanism involving nucleophilic hydride attack,<sup>10-13</sup> we have set out to investigate the catalytic effectiveness of Ru NHC species containing

increasingly more nucleophilic Ru-H ligands. Very recently, we reported an example of such a species in the form of the mixed carbene-phosphine complex

$[\text{Ru}(\text{IEt}_2\text{Me}_2)_2(\text{PPh}_3)_2\text{H}_2]$  (**1**;  $\text{IEt}_2\text{Me}_2 = 1,3\text{-diethyl-4,5-dimethylimidazol-2-ylidene}$ ).<sup>14</sup>

The unusual *trans*-arrangement of the two hydride ligands imparts highly nucleophilic character to Ru-H, as evidenced by the formation of methane and

$[\text{Ru}(\text{IEt}_2\text{Me}_2)_2(\text{PPh}_3)_2\text{HI}]$  upon addition of the electrophile MeI. We now report our initial findings on both the stoichiometric and catalytic reactivity of **1** towards aromatic fluorocarbons. As hoped for, the complex displays high activity for the catalytic HDF of  $\text{C}_6\text{F}_6$ , undergoing up to five HDF steps in generating fluorobenzene.

## Results and Discussion

### Stoichiometric C-F and C-H activation of $\text{C}_6\text{F}_6$ and $\text{C}_6\text{F}_5\text{H}$ by **1**

Monitoring by  $^{31}\text{P}\{^1\text{H}\}$  NMR spectroscopy the room temperature reaction of  $[\text{Ru}(\text{IEt}_2\text{Me}_2)_2(\text{PPh}_3)_2\text{H}_2]$  (**1**) with 10 eq of either  $\text{C}_6\text{F}_6$  or  $\text{C}_6\text{F}_5\text{H}$  in  $\text{C}_6\text{H}_6$  solution<sup>15</sup> showed, over the course of *ca.* 5 h, complete loss of starting material and the appearance of two new product peaks at  $\delta$  45 and 59. These were assigned to the hydride fluoride complex  $[\text{Ru}(\text{IEt}_2\text{Me}_2)_2(\text{PPh}_3)_2\text{HF}]$  (**2**) and the pentafluorophenyl complex  $[\text{Ru}(\text{IEt}_2\text{Me}_2)_2(\text{PPh}_3)(\text{C}_6\text{F}_5)\text{H}]$  (**3**) respectively (Scheme 2). The formation of the two products, which were present after 5 h in an approximate ratio (by  $^{31}\text{P}\{^1\text{H}\}$  NMR spectroscopy) of 1:0.2 from  $\text{C}_6\text{F}_6$  and 1:0.5 from  $\text{C}_6\text{F}_5\text{H}$ , arise from competing C-F and C-H activation respectively. C-H activation proved to be reversible. Thus, addition of  $\text{H}_2$  (4 atm) to an in-situ generated mixture of **2**, **3** and  $\text{PPh}_3$  led to the complete disappearance

of **3** over 4 h at room temperature. In a more controlled experiment, addition of 4 atm H<sub>2</sub> to a solution containing an isolated, crystalline sample of **3** (vide infra) and an equivalent of PPh<sub>3</sub> led to the complete conversion of the former to a mixture of **1** and **2** within 4 h at 298 K. Generation of the latter could be rationalised following analysis of the <sup>1</sup>H and <sup>19</sup>F NMR spectra of the volatile materials from the C<sub>6</sub>F<sub>6</sub> reaction. This revealed the presence of the hydrodefluorination products C<sub>6</sub>F<sub>5</sub>H (major species) and both 1,2,3,4- and 1,2,4,5-C<sub>6</sub>F<sub>4</sub>H<sub>2</sub>, indicating that **1** must initially activate the C-F bond in C<sub>6</sub>F<sub>6</sub> to give **2** and C<sub>6</sub>F<sub>5</sub>H, which then proved to be at least as reactive a substrate as C<sub>6</sub>F<sub>6</sub>, undergoing C-F activation to give the tetrafluorobenzene isomers (and additional **2**), as well as C-H activation to produce **3**. The competitive nature of C-H activation is clearly shown by the higher ratio of **3**:**2** formed in the reaction of **1** with C<sub>6</sub>F<sub>5</sub>H.<sup>16</sup>

Both **2** and **3** could be isolated from the reaction mixture following removal of the volatile components and recrystallization of the residue. The X-ray structure of **2** (Figure 1) revealed retention of the *cis* arrangement of the two NHC ligands and two PPh<sub>3</sub> groups

from **1** and, as a result, very little change in either Ru-C/Ru-P distances and angles. Of particular interest was the long Ru-F distance of 2.264(2) Å. This is comparable to the value (2.284(5) Å) in [Ru(dmpe)<sub>2</sub>H(FHF)] (dmpe = 1,2-bis(dimethylphosphino)ethane), which is the only other *trans* H-Ru-F complex we could find that has been structurally verified.<sup>17</sup> Surprisingly, crystallographically characterised examples of Ru(L)<sub>4</sub>H(halide) (L = PR<sub>3</sub> or NHC) species with *trans* H-Ru-halide geometries in general are not that common,<sup>18</sup> despite complexes of this type being known for over 50 years.<sup>19</sup> Elongation in the Ru-F distance in both **2** and [Ru(dmpe)<sub>2</sub>H(FHF)] compared to those in *cis*-[Ru(dppp)<sub>2</sub>F<sub>2</sub>] (dppp = 1,4-bis(diphenylphosphino)ethane) and *trans*-[Ru(dppe)<sub>2</sub>F<sub>2</sub>] (dppe = 1,2-bis(diphenylphosphino)ethane) of 2.056(3)/2.069(3) and 2.1729(18) Å respectively<sup>20</sup> presumably results from the presence of a *trans*-labilising hydride ligand.

**Fig. 1** Molecular structure of **2**. Solvent, minor disordered component and hydrogen atoms (with the exception of the hydride ligand) have been omitted for clarity. Ellipsoids

are shown at the 30% probability level. Selected bond lengths (Å) and angles (°): Ru(1)-C(1) 2.115(2), Ru(1)-C(10) 2.109(2), Ru(1)-P(1) 2.3343(6), Ru(1)-P(2) 2.3493(6), Ru(1)-F(1) 2.264(2), P(1)-Ru(1)-P(2) 98.66(2), C(1)-Ru(1)-P(1) 170.54(6), C(10)-Ru(1)-F(1) 91.64(8).

A very clear low frequency doublet of triplets Ru-H signal was apparent for **2** in the room temperature  $^1\text{H}$  NMR spectrum in toluene- $d_8$  at  $\delta$  -21.7 (with diagnostic  $J_{\text{HF}}$  and  $J_{\text{HP}}$  values of 52.0 and 19.7 Hz respectively). The  $\text{IEt}_2\text{Me}_2$  signals were broad and overlapping, but resolved upon cooling to 228 K into eight sets of N- $\text{CH}_2$  and four sets N- $\text{CH}_2\text{CH}_3$  signals respectively. The hydride signal at 228 K now appeared as a doublet of doublets ( $J_{\text{HF}} = 51.6$  Hz,  $J_{\text{HP}} = 25.6$  Hz,  $J_{\text{HP}} = 14.1$  Hz), indicating that the two  $\text{PPh}_3$  ligands became inequivalent at low temperature. In line with this, the  $^{31}\text{P}\{^1\text{H}\}$  spectrum changed from a broad singlet at room temperature to what is best described as two very broad, overlapping multiplets spread over *ca.* 1 ppm at 228 K. We were unable to resolve  $J_{\text{PP}}$  or  $J_{\text{PF}}$  splittings even at this low temperature. The  $^{19}\text{F}$  NMR spectrum showed a broad fluoride resonance at  $\delta$  -354 in both THF- $d_8$  and toluene- $d_8$  at room temperature, although the doublet hydride splitting of *ca.* 52 Hz was partially resolved in the THF case. Altering the temperature over the range 248-318 K failed to resolve any further couplings, while the addition of CsF also made no effect.<sup>21</sup>

The X-ray structure of the second product, the bis- $\text{IEt}_2\text{Me}_2$  pentafluorophenyl complex  $[\text{Ru}(\text{IEt}_2\text{Me}_2)_2(\text{PPh}_3)(\text{C}_6\text{F}_5)\text{H}]$  (**3**), revealed the anticipated square based pyramidal geometry, with the hydride *trans* to the vacant site (Figure 2). The two carbenes were now oriented *trans* to one another, forcing the  $\text{PPh}_3$  and fluoroaryl ring

also to be *trans*. The combination of (i) the nature of the *trans* ligand and (ii) the coordinative unsaturation of the metal centre impacted upon the Ru-C<sub>fluoroaryl</sub> bond length, which was shorter (2.136(4) Å) than that found in related systems.<sup>11,12</sup>

**Fig. 2** Molecular structure of **3**. All hydrogen atoms, except for Ru-H, are omitted for clarity. Ellipsoids are shown at the 30% probability level. Selected bond lengths (Å) and angles (°): Ru(1)-C(1) 2.090(3), Ru(1)-C(10) 2.088(3), Ru(1)-C(19) 2.136(4), Ru(1)-P(1) 2.2783(11), C(1)-Ru(1)-C(10) 173.39(15), C(1)-Ru(1)-C(19) 88.43(14).

The positioning of the hydride opposite a vacant site reflected in the solution spectroscopic properties of the compound, in particular, the very low frequency hydride chemical shift of  $\delta$  -33.0. This appeared as a doublet of triplets, with a typical *cis*-<sup>31</sup>P

doublet splitting of 30.6 Hz, and a triplet splitting of 7.2 Hz arising from interaction with the two *ortho*-fluorine atoms of the C<sub>6</sub>F<sub>5</sub> ring.

Efforts to accelerate the reaction of **1** with C<sub>6</sub>F<sub>5</sub>H using higher temperatures resulted instead in the isolation of the bis-phosphine pentafluorophenyl complex [Ru(IEt<sub>2</sub>Me<sub>2</sub>)(PPh<sub>3</sub>)<sub>2</sub>(C<sub>6</sub>F<sub>5</sub>)H] (**4**, Scheme 2) as the major ruthenium containing product of the reaction following overnight heating at 343 K. It was found that **4** could also be formed at room temperature, although very much as the minor partner alongside **2** and **3** if a sample of **1** and C<sub>6</sub>F<sub>6</sub> (10 eq) was left at room temperature for *ca.* 100 h (ratio **2**: **3**: **4** = 1:0.4:0.1). Heating an isolated sample of **3** with PPh<sub>3</sub> (2 eq) at 343-363 K in C<sub>6</sub>H<sub>6</sub> for 5 h failed to give **4**, implying (unsurprisingly)<sup>22</sup> that simple substitution of NHC by phosphine does not account for the formation of **4**.

Crystals of the red compound **4** suitable for X-ray crystallography were isolated from benzene/hexane and displayed the structure shown in Figure 3. Most noticeable was the distorted octahedral geometry now present that resulted from an agostic interaction involving one of the NHC-Et groups occupying the site opposite the Ru-H. The need for the agostic stabilisation must reflect the instability of the five-coordinate 16e Ru(II) species upon replacing the strongly donating IEt<sub>2</sub>Me<sub>2</sub> ligand in **3** for PPh<sub>3</sub> in forming **4**. The agostic distances (Ru...C(5), 2.752 Å; Ru...H(5A), 2.052 Å) lie in between those in the related NHC complexes [Ru(I<sup>i</sup>Pr<sub>2</sub>Me<sub>2</sub>)<sub>2</sub>(I<sup>i</sup>Pr<sub>2</sub>Me<sub>2</sub>)'Cl] and [Ru(IEt<sub>2</sub>Me<sub>2</sub>)(PPh<sub>3</sub>)<sub>2</sub>HCl] previously described by our group<sup>23</sup> and are within the range considered to be strong interactions.<sup>24</sup> The Ru-C distance to the pentafluorophenyl ligand was 2.160(2) Å.

Evidence for the agostic interaction being retained in solution was apparent from small, but very clear, doublet <sup>19</sup>F splittings on low frequency resonances for Ru...H-C at δ

0.5 and  $\delta$  6.4 in the  $^1\text{H}$  and  $^{13}\text{C}\{^1\text{H}\}$  NMR spectra respectively. Use of  $^1\text{H}$ - $^{19}\text{F}$  HMBC spectroscopy established that the coupling resulted from the *ortho*-F signal at  $\delta$  -112 (see ESI). The hydride resonance in **4** ( $\delta$  -24.7) resonated to higher frequency of that in five-coordinate (non-agostic) **3**, and appeared as triplet of doublets, the doublet splitting now arising from coupling to the other *ortho*-F signal at  $\delta$  -106 (see ESI). These couplings help to emphasise the restricted rotation of the  $\text{C}_6\text{F}_5$  ring suggested by the steric crowding in the crystal structure and proven by the presence of five different  $^{19}\text{F}$  NMR resonances.

**Fig. 3** Molecular structure of **4**. All hydrogen atoms, except Ru-H and those in the agostic methyl group, are omitted. Ellipsoids are shown at the 30% probability level. Selected bond lengths ( $\text{\AA}$ ) and angles ( $^\circ$ ): Ru(1)-C(1) 2.060(2), Ru(1)-C(10) 2.160(2), Ru(1)-P(1) 2.3452(6), Ru(1)-P(2) 2.3188(6), P(1)-Ru(1)-P(2) 168.093(19), C(10)-Ru(1)-P(1) 91.56(6), C(1)-Ru(1)-P(2) 89.41(6).

## Formation of **2** via reaction of **1** with 'HF'

In an effort to find a higher yielding route to the hydride fluoride complex **2**, the reaction of **1** with Et<sub>3</sub>N·3HF (TREAT-HF) was investigated. This reagent has become quite commonplace for the formation of transition metal bifluoride ([FHF]<sup>-</sup>) complexes,<sup>25</sup> but has, on occasion, also produced metal fluoride species.<sup>26</sup> As shown in Scheme 3, **2** was formed as the sole Ru containing product upon reaction of **1** with Et<sub>3</sub>N·3HF in a precise 1:1 ratio (i.e. 0.33 eq TREAT-HF). However, increasing the stoichiometry to 1:3 Ru:HF gave instead the previously reported cation [Ru(IEt<sub>2</sub>Me<sub>2</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>H]<sup>+</sup>,<sup>14</sup> which was shown crystallographically to be formed as the relatively unusual [H<sub>2</sub>F<sub>3</sub>]<sup>-</sup> salt, **5** (see ESI).<sup>27</sup>

Scheme 3

## Catalytic HDF using **1**

Initial catalytic studies have shown that **1** is far more active for HDF than our previously reported [Ru(NHC)(PPh<sub>3</sub>)<sub>2</sub>(CO)H<sub>2</sub>] system<sup>10,11</sup> bearing unsaturated or

saturated N-aryl substituted carbenes. As shown in Scheme 4, this reacted via initial phosphine loss to give 16-electron  $[\text{Ru}(\text{NHC})(\text{PPh}_3)(\text{CO})\text{H}_2]$ , which was converted to the hydride fluoride complex  $[\text{Ru}(\text{NHC})(\text{PPh}_3)(\text{CO})\text{HF}]$  following hydrodefluorination. Back reaction with the alkylsilane reductant regenerated the dihydride complex, forming a strong Si-F bond in  $\text{R}_3\text{SiF}$  in the process which provides the driving force for the reaction.

Scheme 4

The mixture of C-F and C-H activation products formed in the stoichiometric reaction of **1** and  $\text{C}_6\text{F}_6$  suggests that the first step of a comparable catalytic cycle with **1** might be more complex, and so the individual stoichiometric reactions of **2**, **3** and **4** with  $\text{Et}_3\text{SiH}$  were investigated to establish the viability of the return reduction steps necessary to complete the catalytic cycle. It was found that: (i) Treatment of the hydride fluoride complex **2** with 1 eq  $\text{Et}_3\text{SiH}$  led to the instantaneous reformation of **1**, along with  $\text{Et}_3\text{SiF}$ ; (ii) There was no reaction between **3** and  $\text{Et}_3\text{SiH}$  (1.5 eq) at room temperature over 6 h, or even upon heating at 343 K for 4 h; (iii) No reaction occurred between the bis-phosphine fluoroaryl complex **4** and silane (1.5 eq) at room temperature overnight, although following addition of  $\text{I}(\text{Et}_2\text{Me})_2$  (5 eq), both  $\text{C}_6\text{F}_4\text{H}_2$  and  $\text{Et}_3\text{SiF}$  appeared very quickly in

the  $^{19}\text{F}$  NMR spectrum. Over the course of *ca.* 2 h, however, the sample began to decompose, shown by the deposition of black solid material

**Fig. 4** Product distribution from the catalytic HDF of  $\text{C}_6\text{F}_6$  using 10 mol% **1** with 80 eq  $\text{Et}_3\text{SiH}$  in  $\text{C}_6\text{H}_6$  at 363 K. Reactions run under (top line) Ar (1 atm) and (bottom line)  $\text{H}_2$  (4 atm) with percentage of products (average of 3 runs) shown after 72 h and (in parentheses) 144 h. HDF products were assigned by  $^{19}\text{F}$  NMR spectroscopy.

Figure 4 shows the product distribution from the HDF of  $\text{C}_6\text{F}_6$  with 10 mol% **1** carried out with  $\text{Et}_3\text{SiH}$  as reductant (80 eq) in  $\text{C}_6\text{H}_6$  at 363 K. The elevated temperature was adopted in an effort to both push catalysis through at a reasonable rate and also to try to drive HDF through to lower fluorine containing products, which are typically more

difficult to obtain.<sup>28</sup> Remarkably, **1** proved capable of bringing about three and four HDF steps to a significant extent, affording 96% of the reaction mixture as isomers of tri- and difluorobenzenes over 72 h.<sup>29</sup> Doubling the reaction time increased the amount of 1,2- and 1,4-C<sub>6</sub>F<sub>2</sub>H<sub>4</sub> and even generated a small amount of fluorobenzene through completion of five HDF steps, giving an overall turnover number of 37. While an in-depth study of the regioselectivity of HDF remains to be carried out, the presence of both 1,2,4,5- and 1,2,3,4-isomers of C<sub>6</sub>F<sub>4</sub>H<sub>2</sub> after 72 h suggests that the very high *ortho*-regioselectivity found with [Ru(NHC)(PPh<sub>3</sub>)<sub>2</sub>(CO)H<sub>2</sub>] (which converted C<sub>6</sub>F<sub>5</sub>H overwhelmingly to 1,2,3,4-C<sub>6</sub>F<sub>4</sub>H<sub>2</sub>) is less apparent with **1**. When HDF of C<sub>6</sub>F<sub>6</sub> was repeated but now under 4 atm H<sub>2</sub>, the amount of difluorobenzene products increased (TON = 38), while the relative ratio of the 1,2:1,3:1,4 difluorobenzene isomers also altered. Interestingly, no turnover of the reaction between C<sub>6</sub>F<sub>6</sub> and 10 mol% **1** took place under 4 atm H<sub>2</sub>/ excess NEt<sub>3</sub> (80 equivalents)<sup>30</sup> in the absence of the silane.

## Conclusions

In conclusion, we have shown that [Ru(IEt<sub>2</sub>Me<sub>2</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>H<sub>2</sub>] (**1**) is a far more active catalyst for the hydrodefluorination of C<sub>6</sub>F<sub>6</sub> than the previously reported [Ru(NHC)(PPh<sub>3</sub>)(CO)H<sub>2</sub>] systems, as reflected in the reduction of C<sub>6</sub>F<sub>6</sub> down as far as fluorobenzene. Given the previous mechanistic studies on Ru-H catalysed HDF, this enhanced activity most likely arises from the greater nucleophilicity of the hydride ligands in **1**, arising as a result of their *trans* H-Ru-H geometry. A mechanistic study of **1** is ongoing to confirm the role of the Ru-H bond, and also to help rationalise the lower

regioselectivity compared to  $[\text{Ru}(\text{NHC})(\text{PPh}_3)(\text{CO})\text{H}_2]$ . Moreover, we hope to be able to explain why **1** is so catalytically competent in spite of appearing, at least on the basis of stoichiometric experiments, to be far more prone than  $[\text{Ru}(\text{NHC})(\text{PPh}_3)(\text{CO})\text{H}_2]$  to unfavourable C-H activation reactions with partially fluorinated substrates like  $\text{C}_6\text{F}_5\text{H}$ . Given that the catalysis was run under high temperature conditions where C-H activated products like  $[\text{Ru}(\text{IEt}_2\text{Me}_2)(\text{PPh}_3)_2(\text{C}_6\text{F}_5)\text{H}]$  (**4**) are observed, one possibility is that such species are not dead-ends, but can be recycled into the catalytic cycle, allowing propagation of HDF to continue. While this may help to explain the bias towards more of the lower fluorine containing products with a moderate pressure of  $\text{H}_2$  shown in Figure 4, it fails to explain the change in isomer distribution. We hope to present answers to these questions in the near future.

## Experimental

### General considerations

All manipulations were carried out using standard Schlenk, high vacuum and glovebox techniques. Solvents were purified using an MBraun SPS solvent system (hexane,  $\text{Et}_2\text{O}$ ) or under a nitrogen atmosphere from sodium benzophenone ketyl (benzene).  $\text{C}_6\text{D}_6$  and  $\text{C}_6\text{D}_5\text{CD}_3$  were vacuum transferred from potassium. NMR spectra were recorded on Bruker Avance 400/500 and Avance III 500 MHz NMR spectrometers and referenced as follows:  $^1\text{H}$ ,  $\delta$  7.15 ( $\text{C}_6\text{D}_5\text{H}$ ),  $\delta$  2.09 ( $\text{C}_6\text{D}_5\text{CD}_2\text{H}$ ) and  $\delta$  3.58 ( $\text{THF-}d_7$ );  $^{13}\text{C}\{^1\text{H}\}$ ,  $\delta$  128.0 ( $\text{C}_6\text{D}_6$ ) and  $\delta$  21.3 ( $\text{C}_6\text{D}_5\text{CD}_3$ );  $^{31}\text{P}\{^1\text{H}\}$ , externally to 85%  $\text{H}_3\text{PO}_4$  ( $\delta$  0.0);  $^{19}\text{F}$ , externally to  $\text{CFCl}_3$  ( $\delta$  0.0).  $\text{PPh}_3$  resonances are excluded unless they could be assigned unequivocally. Elemental analyses were performed by Elemental Microanalysis Ltd,

Okehampton, Devon.  $[\text{Ru}(\text{PPh}_3)_4\text{H}_2]$ <sup>31</sup> and  $\text{IEt}_2\text{Me}_2$ <sup>32</sup> were prepared according to literature methods.

**$[\text{Ru}(\text{IEt}_2\text{Me}_2)_2(\text{PPh}_3)_2\text{H}_2]$  (1).** An alternative synthesis of **1** carried out in benzene rather than as previously described<sup>14</sup> in THF is reported here. This new approach afforded **1** in shorter time and in higher yield.  $[\text{Ru}(\text{PPh}_3)_4\text{H}_2]$  (500 mg, 0.43 mmol) and  $\text{IEt}_2\text{Me}_2$  (130 mg, 0.86 mmol) were dissolved in benzene (5 mL) and stirred in an ampoule sealed with a J. Youngs PTFE tap for 5 min at 298 K. The solution was filtered by cannula into a fresh ampoule and the volatiles were removed *in vacuo* to leave a sticky orange residue. This was washed with hexane (2 x 2 mL) to afford **1** as pale yellow solid. Yield: 279 mg, 70 %. Spectroscopic data matched those in the original report.<sup>14</sup>

**$[\text{Ru}(\text{IEt}_2\text{Me}_2)_2(\text{PPh}_3)_2\text{HF}]$  (2).**  $\text{C}_6\text{F}_6$  (50  $\mu\text{L}$ , 0.45 mmol) was added to a benzene (5 mL) solution of **1** (140 mg, 0.15 mmol) in an ampoule fitted with J. Youngs PTFE tap. The reaction mixture was stirred vigorously for 24 h, filtered by cannula and evaporated to dryness to afford an oily red residue. Addition of hexane (1 mL) under the action of vigorous stirring resulted in a formation of a deep orange suspension (of **3**), which was filtered by cannula. Leaving the hexane filtrate at room temperature for few days afforded yellow crystals of **2**, which were manually separated from red needles of residual **3**. Yield of **2**: 43 mg, 30 %. A more efficient route to **2** involved treatment of **1** with  $\text{Et}_3\text{N}\cdot 3\text{HF}$  (TREAT-HF). Thus, TREAT-HF (6.1  $\mu\text{L}$ , 0.037 mmol) was added by syringe to a benzene solution (5 mL) of **1** (100 mg, 0.11 mmol) in an ampoule fitted with a J. Youngs PTFE tap. The reaction mixture was stirred for 30 min, the volatiles then removed under vacuum and the sticky yellow solid washed with hexane (2 mL) to afford **2** as a pale yellow solid. Yield: 75 mg, 72 %. <sup>1</sup>H NMR:  $\delta_{\text{H}}$  ( $\text{C}_6\text{D}_5\text{CD}_3$ , 400 MHz, 228 K) -21.58

**[Ru(IEt<sub>2</sub>Me<sub>2</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>H][H<sub>2</sub>F<sub>3</sub>] (5)**. TREAT-HF (17.5 μL, 0.11 mmol) was added to a benzene (5 mL) solution of **1** (100 mg, 0.11 mmol) in a J. Youngs resealable ampoule. The reaction mixture was stirred at room temperature for 30 min at 298 K, before the sample was reduced to dryness. The sticky orange/red residue was washed with hexane (2 x 2 mL) and Et<sub>2</sub>O (2 x 2 mL) and then redissolved in THF (5 mL). Addition of Et<sub>2</sub>O resulted in the precipitation of **5** as an orange solid, which was washed further with Et<sub>2</sub>O (2 x 5 mL) and then dried *in vacuo*. Yield: 76 mg, 69%. Crystals suitable for X-ray diffraction were obtained upon layering a concentrated THF-*d*<sub>8</sub> solution with hexane. <sup>1</sup>H NMR: δ<sub>H</sub> (THF-*d*<sub>8</sub>, 500 MHz, 298 K) -29.65 (1H, t, *J*<sub>HP</sub> = 24.0 Hz, Ru-*H*), 0.44 (6H, t, *J*<sub>HH</sub> = 7.3 Hz, NCH<sub>2</sub>CH<sub>3</sub>), 0.88 (6H, t, *J*<sub>HH</sub> = 7.3 Hz, NCH<sub>2</sub>CH<sub>3</sub>), 1.81 (6H, s, NCCH<sub>3</sub>), 2.01 (6H, s, NCCH<sub>3</sub>), 2.75 (4H, q, *J*<sub>HH</sub> = 7.3 Hz, NCH<sub>2</sub>CH<sub>3</sub>), 3.36 (4H, q, *J*<sub>HH</sub> = 7.3 Hz, NCH<sub>2</sub>CH<sub>3</sub>), 7.16-7.34 (30H, m, P(C<sub>6</sub>H<sub>5</sub>)<sub>3</sub>), 13.68 (2H, br s, [H<sub>2</sub>F<sub>3</sub>]<sup>-</sup>). <sup>31</sup>P {<sup>1</sup>H} NMR: δ<sub>P</sub> (THF-*d*<sub>8</sub>, 202 MHz, 298 K) 46.1 (s). <sup>19</sup>F NMR: δ<sub>F</sub> (THF-*d*<sub>8</sub>, 470 MHz, 298 K) -115.2 (br s). Analysis found: C, 64.38; H, 5.69; N, 4.84.

C<sub>54</sub>H<sub>65</sub>N<sub>4</sub>F<sub>3</sub>P<sub>2</sub>Ru·2C<sub>4</sub>D<sub>8</sub>O requires C, 64.73; H, 5.70; N, 4.87.

**Procedures for Catalytic HDF.** A stock solution of **1** was prepared by dissolving 0.0184 g (0.02 mmol) of the complex in 2 mL C<sub>6</sub>H<sub>6</sub> in the glovebox. 0.5 mL aliquots of this solution was syringed into three J. Young's resealable NMR tubes, and C<sub>6</sub>F<sub>6</sub> (5.8 μL, 0.05 mmol) and Et<sub>3</sub>SiH (63 μL, 0.4 mmol) added to each tube. These were then placed in a pre-heated oil bath at 363 K and monitored by <sup>19</sup>F NMR spectroscopy after 72 and 144 h. For reactions performed under H<sub>2</sub>, a C<sub>6</sub>H<sub>6</sub> (0.3 mL) sample of **1** (0.0046 g, 0.005

mmol) was placed into a medium-walled NMR tube fitted with a resealable valve and freeze-pump-thaw degassed (3 cycles). A mixture of C<sub>6</sub>F<sub>6</sub> (5.8 μL, 0.05 mmol), Et<sub>3</sub>SiH (63 μL, 0.4 mmol) and C<sub>6</sub>H<sub>6</sub> (0.1 mL) was vacuum transferred into the pressure tube, which was then put under 4 atm H<sub>2</sub> and placed in a pre-heated oil bath at 363 K. The reaction was monitored by <sup>19</sup>F NMR spectroscopy after 72 and 144 h.

**X-ray crystallography.** Data for **2** and **4** were obtained using a Nonius Kappa CCD diffractometer, while those for **3** and **5** (see ESI) were collected using Agilent SuperNova and Agilent Excalibur diffractometers, respectively. Details of the data collections, solutions and refinements are given in Table 1. All diffraction measurements were conducted at 150 K using Mo(Kα) radiation and hydride ligands were uniformly refined subject to being a distance of 1.6 Å from the relevant metal centre. Convergence was straightforward in all cases, and only exceptional details merit note. In particular, the asymmetric unit in **2** was seen to comprise one bis-carbene complex and half of a hexane molecule. The latter is proximate to an inversion centre which serves to generate the remainder. The fluoride and hydride ligands were modelled subject to being disordered with each other in a 53:47 ratio. Fractional occupancy hydride atoms were refined with a common isotropic displacement parameter. In **3**, H5A, H5B and H5C were readily located and refined with the single restraint of being at a distance of 0.98 Å from C5. The structures were solved using SHELXS-97<sup>33</sup> and refined using full-matrix least squares in SHELXL-97.<sup>33</sup> Crystallographic data for compounds have been deposited with the Cambridge Crystallographic Data Centre as supplementary publications CCDC 1400863-1400866. Copies of the data can be obtained free of charge on application to CCDC, 12

## Graphical Abstract

Stoichiometric and Catalytic C-F Bond Activation by the *Trans*-Dihydride NHC

Complex  $[\text{Ru}(\text{IEt}_2\text{Me}_2)_2(\text{PPh}_3)_2\text{H}_2]$  ( $\text{IEt}_2\text{Me}_2 = 1,3\text{-diethyl-4,5-dimethylimidazol-2-ylidene}$ )

Mateusz K. Cybulski, Ian M. Riddlestone, Mary F. Mahon, Timothy J. Woodman and Michael K. Whittlesey

Multiple catalytic hydrodefluorination steps take place with the *trans*-dihydride complex  $[\text{Ru}(\text{IEt}_2\text{Me}_2)_2(\text{PPh}_3)_2\text{H}_2]$  (**1**), taking  $\text{C}_6\text{F}_6$  to tri-, di- and mono-fluorobenzenes.
