On the graphic matroid parity problem

Zoltán Szigeti*

Abstract

A relatively simple proof is presented for the min-max theorem of Lovász on the graphic matroid parity problem.

1 Introduction

The graph matching problem and the matroid intersection problem are two well-solved problems in Combinatorial Theory in the sense of min-max theorems [2], [3] and polynomial algorithms [4], [3] for finding an optimal solution. The matroid parity problem, a common generalization of them, turned out to be much more difficult. For the general problem there does not exist polynomial algorithm [6], [8]. Moreover, it contains NP-complete problems. On the other hand, for linear matroids Lovász provided a min-max formula in [7] and a polynomial algorithm in [8]. There are several earlier results which can be derived from Lovász’ theorem, e.g. Tutte’s result on f-factors [15], a result of Mader on openly disjoint A-paths [11] (see [9]), a result of Nebesky concerning maximum genus of graphs [12] (see [5]), and the problem of Lovász on cacti [9]. This latter one is a special case of the graphic matroid parity problem. Our aim is to provide a simple proof for the min-max formula on this problem, i.e. on the graphic matroid parity problem. In an earlier paper [14] of the present author the special case of cacti was considered. We remark that we shall apply the matroid intersection theorem of Edmonds [4]. We refer the reader to [13] for basic concepts on matroids.

For a given graph $G$, the cycle matroid $\mathcal{G}$ is defined on the edge set of $G$ in such a way that the independent sets are exactly the edge sets of the forests of $G$. Thus, for the rank function $r_G$ of $\mathcal{G}$ and for an edge set $F$ of $G$,

$$r_G(F) = |V(G)| - c(G[F]),$$

where $c(H)$ denotes the number of connected components of a graph $H$ and $G[F] = (V(G), F)$. In other words, $r_G(F)$ is the maximum size of a forest contained in $F$. A matroid $\mathcal{M}$ is graphic if there exists a graph whose cycle matroid is $\mathcal{M}$.

The graphic matroid parity problem is the following. Given a graph $G$ and a partition $\mathcal{V}$ of its edge set into pairs, what is the maximum size of a forest which consists of pairs in $\mathcal{V}$. The pair $(G, \mathcal{V})$ is called a v-graph. A v-forest of $(G, \mathcal{V})$ is a forest of $G$ consisting of v-pairs in $\mathcal{V}$. The v-size of a v-forest is the number of v-pairs contained in it. The graphic matroid parity problem consists of finding the maximum v-size $\beta(G, \mathcal{V})$ of a v-forest in a v-graph $(G, \mathcal{V})$.

Let $(G, \mathcal{V})$ be a v-graph. Let $\mathcal{P} := \{V_1, V_2, ..., V_l\}$ be a partition of the vertex set $V(G)$ and let $\mathcal{Q} := \{H_1, H_2, ..., H_k\}$ be a partition of $\mathcal{V}$. We say that $(\mathcal{P}, \mathcal{Q})$ is a cover of $(G, \mathcal{V})$. For a partition $\mathcal{P}$ of $\mathcal{V}$, $\mathcal{V}_{\mathcal{P}}$ will denote the vertex set obtained from $V$ by contracting each set $V_i$ in $\mathcal{P}$ into one vertex $v_i$. Note that $|\mathcal{V}_{\mathcal{P}}| = |\mathcal{P}| = l$. Let $G_{\mathcal{P},\mathcal{Q}} := (\mathcal{V}_{\mathcal{P}}, E(G))$. For $H_i \subseteq \mathcal{V}$, $(G_{\mathcal{P},\mathcal{Q}}[H_i], H_i)$ will denote the v-graph on the vertex set $V_{\mathcal{P}}$ for which the edge set $E(H_i)$ of $G_{\mathcal{P},\mathcal{Q}}[H_i]$ is the union of the edges of the v-pairs in $H_i$. For $H_i \subseteq \mathcal{V}$, let $r_{\mathcal{P}}(H_i) := r_{G_{\mathcal{P},\mathcal{Q}}}(E(H_i)) = l - c(G_{\mathcal{P},\mathcal{Q}}[H_i])$. The value $\text{val}(\mathcal{P}, \mathcal{Q})$ of a cover is defined as follows. Let $n = |V(G)|$, $l = |\mathcal{P}|$ and $k = |\mathcal{Q}|$.

$$\text{val}(\mathcal{P}, \mathcal{Q}) := n - l + \sum_{H_i \in \mathcal{Q}} \frac{r_{\mathcal{P}}(H_i)}{2}.$$  

Now, we are able to present the min-max result of Lovász [7] in our terminology.

*Equipe Combinatoire, Université Paris 6, 75252 Paris, Cedex 05, France
Theorem 1 Let $(G, V)$ be a v-graph. Then $\beta(G, V) = \min\{val(\mathcal{P}, \mathcal{Q})\}$, where the minimum is taken over all covers $(\mathcal{P}, \mathcal{Q})$ of $(G, V)$.

We mention that the min-max formula for the special case of cacti is presented in [10] in Theorem 11.3.6. Theorem 1 is the natural generalization of that formula. To see that the problem of cacti, i.e. finding a maximum triangular cactus in a graph $G$, is a special case of the graphic matroid parity problem we have to consider the v-graph $(G', V)$ which is defined by the original graph $G$ as follows: Let us denote by $T$ the set of triangles of $G$. For every $T \in T$, let $e_T, f_T$ be two edges of $T$. Let $\mathcal{V} := \{(e_T, f_T) : T \in T\}$ and let $G' := (V(G), E(G'))$ where $E(G') := \bigcup_{T \in T} \{e_T, f_T\}$ where the union is understood by multiplicity.

Our proof follows the line of Gallai’s (independently Anderson’s [1]) proof for Tutte’s theorem on the existence of perfect matchings.

2 Definitions

A v-forest $F$ of a v-graph $(G, V)$ is called perfect if it is a spanning forest of $G$, that is $|F| = rc(G(E(G)))$. A forest $F$ is said to be almost spanning if $|F| = rc(G(E(G))) - 1$. A v-forest is almost perfect if it is almost spanning. For an edge set $F$ of a v-graph $(G, V)$, the maximum v-size of a v-forest contained in $F$ is denoted by $v_F(F)$. Note that

$$v_F(F) \leq \left\lfloor \frac{rc(G)}{2} \right\rfloor. \quad (3)$$

A v-graph $(G, V)$ will be called critical if by identifying any two vertices in the same connected component of $G$, the v-graph obtained has a perfect v-forest. In particular, this means that in a critical v-graph there exists an almost perfect v-forest. Critical v-graphs will play an important role in the proof, like factor critical graphs play the key role in the proof of Tutte’s theorem.

For a cover $(\mathcal{P}, \mathcal{Q})$ of a v-graph $(G, V)$, let us denote by $v_{\mathcal{P}}, s_{\mathcal{P}}$ and $r_{\mathcal{P}}$ the sets of v-pairs $T \in V$ for which $r_{\mathcal{P}}(T) = 2, r_{\mathcal{P}}(T) = 1$ and $r_{\mathcal{P}}(T) = 0$. (Then $V = V_{\mathcal{P}} \cup s_{\mathcal{P}} \cup r_{\mathcal{P}}$.) The elements $H_i \in \mathcal{Q}$ with $r_{\mathcal{P}}(H_i) \geq 1$ are called components of the cover. A component $H_i \in \mathcal{Q}$ is said to be critical if the v-graph $(G_{\mathcal{P}}[H_i], H_i)$ is critical.

For a graph $H = (U, F)$ we shall denote by $\sim_H$ the equivalence relation for which $u \sim_H v$ for $u, v \in U$ if and only if there exists a path connecting $u$ and $v$ in $H$. The partition of $U$ defined by the equivalence classes of $\sim_H$, that is by the vertex sets of the connected components of $H$, is denoted by $\text{part}(H)$.

We say that the partition $\mathcal{P}$ of $V(G)$ is the trivial partition if $l = n$ and $k = 1$. Let $\mathcal{P} = \{V_1^1, ..., V_1^n, V_2^1, ..., V_2^n, ..., V_l^1, ..., V_l^n\}$, where $\bigcup_i V_i^1 = V_i$ for all $i$, then the partition $\mathcal{P}$ is called a refinement of the partition $\mathcal{P}$. If $\mathcal{P}'$ is a refinement of $\mathcal{P}$ so that $|\mathcal{P}'| = |\mathcal{P}| + 1$, then we say it is an elementary refinement. If $V_i \in \mathcal{P}$ then the partition obtained from $\mathcal{P}$ by replacing $V_i$ by its singletons will be denoted by $\mathcal{P} / \{V_i\}$. If $\mathcal{P}'$ is a refinement of $\mathcal{P}$, then $\mathcal{P}$ corresponds to a partition of $V(G_{\mathcal{P}'})$. This partition will be denoted by $\mathcal{P} / \mathcal{P}'$.

We shall need later two auxiliary graphs $B$ and $D$. These graphs will depend on a v-graph $(G, V)$ and a cover $(\mathcal{P}, \mathcal{Q})$ of this v-graph. We suppose that for each component $H_i$, $r_{\mathcal{P}}(H_i)$ is odd. First we define the graph $B = (V(G), E(B))$. $e = uv$ will be an edge of $B$ if and only if there exist $u, v \in V_i \in \mathcal{P}$, a component $H_i \in \mathcal{Q}$ and a v-forest $K_i$ in $(G_{\mathcal{P} \cup \{V_j\}}[H_i], H_i)$ of v-size $(r_{\mathcal{P}}(H_i) + 1)/2$ so that $u \sim_{K_i} v$ but for every pair $(x, y) \neq (u, v)$ of vertices from $V_j, x \neq_{K_i} y$. (Note that $(V_P, E(K))$ contains a v-forest of v-size $(r_{\mathcal{P}}(H_i) - 1)/2$ in $(G_P[H_i], H_i)$.) We mention that by Lemma 8, see later) $(G_P[H_i], H_i)$ will always contain a v-forest of v-size $(r_{\mathcal{P}}(H_i) - 1)/2$. In other words, the trace of the v-forest $K_i$ in $V_j \in \mathcal{P}$ is the edge $e$. We call this edge $e$ an augmenting edge for $H_i$. We will call the edges of $B$ augmenting edges. Note that an edge of $B$ may be augmenting for more than one component $H_i \in \mathcal{Q}$. For a refinement $\mathcal{P}'$ of $\mathcal{P}$, the set $A_{\mathcal{P}' \subseteq E(B)}$ of augmenting edges connecting vertices in different sets of $\mathcal{P}'$ will be called the augmenting edges with respect to the refinement $\mathcal{P}'$.

The second auxiliary graph $D$ will be a bipartite graph with colour classes $E(B)$ (the edge set of $B$) and $\mathcal{Q}$. Two vertices $e \in E(B)$ and $H_i \in \mathcal{Q}$ are connected in $D$ by an edge if and only if $e$ is an augmenting edge for $H_i$. As usual, the set of neighbours of a vertex set $X$ of one of the colour classes of $D$ will be denoted by $\Gamma_D(X)$. 
3 Outline of the proof

In this section we present some ideas of the proof. As it was mentioned earlier we shall follow the proof of Tutte’s theorem. Let us briefly summarize the steps of this proof. We suppose that the Tutte condition is satisfied for a given graph \( G \) and we have to construct a perfect matching of \( G \). Let \( X \) be a maximal set satisfying the condition with equality. The maximality of \( X \) implies that all the components of \( G - X \) are factor-critical, thus it is enough to find a perfect matching in an auxiliary bipartite graph \( D \), where one of the color classes corresponds to \( X \) while the other to the (critical) components. Hall’s theorem (or the matroid intersection theorem) provides easily the existence of a perfect matching of the color classes corresponds to \( X \) factor-critical, thus it is enough to find a perfect matching in an auxiliary bipartite graph.

In this section we present some simple properties of forests and of the graphic matroid rank function.

(a) For \( F' \subseteq F \subseteq E \), \( r(F') \leq r(F) \).

(b) For \( F' \subseteq F \), \( r(F' \cup F'') \leq r(F') + r(F'') \).

\[ \Box \]

Lemma 3 Let \( H = (U, F) \) be a graph, let \( \mathcal{P} \) be a partition of \( U \) and let \( F_0 \) be an edge set such that \( part(F_0) = \mathcal{P} \). Then

(a) \( r(F \cup F_0) = r_{\mathcal{P}}(F) + r(F_0) \),

(b) \( r_{\mathcal{P}}(F) \leq r(F) \),

(c) \( r(F) \leq |U| - |\mathcal{P}| + r_{\mathcal{P}}(F) \),

(d) if \( r_{\mathcal{P}}(F) < r(F) \) then there exists an elementary refinement \( \mathcal{P}' \) of \( \mathcal{P} \) such that \( r_{\mathcal{P}'}(F) < r_{\mathcal{P}'}(F) \).

4 Graphic matroid

In this section we present some simple properties of forests and of the graphic matroid rank function.

Claim 2 Let \( H = (U, F) \) be a graph. Then

(a) for \( F'' \subseteq F' \subseteq F \), \( r(F'') \leq r(F') \),

(b) for \( F', F'' \subseteq F \), \( r(F' \cup F'') \leq r(F') + r(F'') \).

\[ \Box \]
Proof. (a) By (1) and by part($F_0$) = $P$, $r(F \cup F_0) = n - c(F \cup F_0) = n - cp(F \cup F_0) = (|P| - cp(F)) + (n - |P|) = r_p(F) + r(F_0)$.
(b) By Lemma 3(a) and Claim 2(b), $r_p(F) = r(F \cup F_0) - r(F_0) \leq r(F)$.
(c) By Claim 2(a) and Lemma 3(a), $r(F) \leq r(F \cup F_0) = r_p(F) + r(F_0) = r_p(F) + |U| - |P|$.
(d) Let $F'$ be a spanning forest of ($V_p$, $F$). Then $r_p(F) = |F'|$. Since $r(F) > r_p(F) = |F'|$ there exists an edge $f \in F - F'$ such that $(V, F' \cup f)$ is a forest. $(V_p, F' \cup f)$ contains a unique cycle $C$ and $f \in E(C)$ because $F'$ is a forest. On the other hand, $(V, F' \cup f)$ contains no cycles so there is a vertex $v_i \in V_p(C)$ such that the two edges of $C$ incident to $v_i$ are incident to different vertices of $V_i$, say a and b. But then for the elementary refinement $P'' := (P - V_i) \cup a \cup (V_i - a)$, $(V_p, F' \cup f)$ is a forest and hence $r_p(F) \geq |F' \cup f| > r(F)$. □

Claim 4 Let $F$ be a forest and let $F_1$ and $F_2$ be two vertex disjoint subtrees of $F$. If $F_1$ and $F_2$ belong to the same connected component of $F$ then let us denote by a and b the two end vertices of the shortest path in $F$ connecting $F_1$ and $F_2$, otherwise let a ∈ $V(F_1)$ and b ∈ $V(F_2)$ be two arbitrary vertices. Then (a) if $F'$ is a forest of size $|F'|$ then $(F - E(F_1)) \cup E(F_2)$ is a forest. (b) If $F'$ is a forest on $V(F_1) \cup V(F_2)$ so that a and b are in different connected components of $F'$, then $(F - E(F_1)) \cup E(F_2)$ is a forest.

The proof of Claim 4 is a simple exercise, it is left to the reader.

Lemma 5 Let $(V, F)$ be a forest. Let $F_0 = \{e_1, ..., e_k\}$, $F_1, ..., F_k$ disjoint edge sets of $F$ and let $F'_1, ..., F'_k$ be disjoint edge sets on $V$. Let $P := $ part$(V, F_0)$. Suppose that for all $1 \leq i \leq k$ the following conditions are satisfied.

(i) $|F'_i| = |F_i| + 1$.
(ii) part($V_p$, $F'_i$) = part($V_p$, $F_i$),
(iii) if $e_i$ is in $V_j$, then $(V_p, V_j, F'_i)$ is a forest whose trace in $V_j$ is $e_i$.

Then $F^* := (F - \bigcup_i F_i) \cup \bigcup_i F'_i$ is a forest of size $|F|$.

Proof. By the disjointness of the sets $F_i$ (resp. $F'_i$), by (i) and by $|F_0| = k$, $|F^*| = |(F - \bigcup_i F_i) \cup \bigcup_i F'_i| = |F| - \sum_i |F_i| + \sum_i |F'_i| = |F| - \sum_i |F_i| - \sum_i |F_i| + \sum_i |F_i| + 1 = |F| - |F_0| - \sum_i |F_i| + \sum_i |F_i| + k = |F|$. By Claim 4(a) applied for each connected component of $F_i$ for every i, we obtain that $r_p(F - F_0) = r_p(F^*)$. Then, by Lemma 3(a), $|F^*| = |F| = r(F) = r((F - F_0) \cup F_0) = r_p(F - F_0) + r(F_0) = r_p(F^*) + r(F_0) = r(F^* + F_0)$. Thus it is enough to prove that $r(F^* + F_0) = r(F^*)$, in other words $u_i \sim_{(V, F^*)} w_i$ for every $u_i, w_i \in F_0$. Suppose on the contrary that there exists an edge $u_j, w_j \in F_0$ (say $u_j, w_j \in V_j$) such that $u_j \not\sim_{(V, F^*)} w_j$. By (iii), $(V_p, V_j, F'_i)$ contains a path $P_j$ connecting $u_j$ and $w_j$. Since $E(P_j) \subset F'_j \supset F^*$ but $u_j \not\sim_{(V, F^*)} w_j$, it follows that there exists a vertex $v_{j2} \in V(P_j)$ ($j_2 \neq j_1$) and an edge $u_{j2}, w_{j2} \in F_0$ (with $u_{j2}, w_{j2} \in V_{j2}$) such that $u_{j2} \not\sim_{(V, F^*)} w_{j2}$. Note that $P_j$ connects $u_{j2}$ and $v_{j2}$ in $(V_p, F'_i)$ and hence, by (i), there exists a path $Q_j$ in $(V_p, F'_i)$ connecting $v_{j2}$ and $v_{j2}$. The same way, there exists an edge $v_{j3}, w_{j3} \in F_0$ ($j_3 \neq j_2$) (say $u_{j3}, w_{j3} \in V_{j3}$) such that $u_{j3} \not\sim_{(V, F^*)} w_{j3}$ and there exists a path $Q_{j3}$ in $(V_p, F'_i)$ connecting $v_{j3}$ and $v_{j3}$. We can continue the same way. Since $|F_0|$ is finite there exist indices $s < t$ such that $v_s = v_{s+1}$. Then using that the paths $Q_i$ connect $v_s$ and $v_{s+1}$ for every $s \leq i \leq t$ in $(V_p, F_p)$ and that these paths are edge disjoint it follows that $C := Q_s \cup Q_{s+1} \cup \ldots \cup Q_t$ is a cycle in $(V_p, F - F_0)$. This is a contradiction because, by Lemma 3(a), $|F - F_0| = |F| - |F_0| = r(F) - r(F_0) = r_p(F - F_0)$ and hence $(V_p, F - F_0)$ is a forest. □

We mention that Lemma 5 will be applied only in the very last step of the proof.

5 The proof

Proof. (max ≤ min) The following lemma proves this direction.

Lemma 6 For a forest $F$ in $G$ and for a cover $(P, Q)$ of $(G, V)$, we have $v_P(F) \leq (n - l) + \sum_{H \in Q} \lfloor \frac{r_p(H)}{2} \rfloor$.

Proof. Let $F'$ be a subset of $F$ of maximum size so that $F'$ is a forest in $G_P$. By Lemma 3(c), $|F'| = r(F) \leq n - l + r_p(F) = n - l + |F'|$. Since the number of $V$-pairs in $F$ is equal to the number of $V$-pairs in $F'$ plus the number of $V$-pairs $f_1, f_2$ in $F$ for which at most one of $f_1$ and $f_2$ belongs to $F'$, we have

$$v_P(F) \leq v_P(F') + |F - F'| \leq v_P(F') + n - l.$$

(4)
For each $H_i \in Q$, let $H'_i := (H_i)_P$ and let $F'_i := F' \cap E(H_i)$. Then $F'_i$ is a forest in $G_P[H_i]$ and so $r_P(F'_i) \leq r_P(H_i)$. Whence, by (3), $v_{H'}(F'_i) \leq \frac{[\frac{r_P(F'_i)}{2}]} {\lfloor \frac{r_P(H_i)}{2} \rfloor}$. As $Q$ is a partition of $V$, for every v-pair $T$ contained in $F'$ there exists some $H_i \in Q$ such that $T \in H'_i$. Thus

$$v_{H'}(F') = \sum_{H_i \in Q} v_{H'}(F'_i) \leq \sum_{H_i \in Q} \left[\frac{r_P(H_i)}{2}\right].$$

(4) and (5) imply the desired inequality. □

**Remark 1.** It follows from the proof of Lemma 6 that if $(P, Q)$ is a cover of $(G, V)$ and $F$ is a $v$-forest of $G$ of size $\text{val}(P, Q)$ then we have equality in (4). It follows that for every $v$-pair $f_1, f_2$ in $F$ at least one of $f_1$ and $f_2$ belongs to $F'$, that is if $T \in R_P$ then $T$ is not contained in $F$.

**Proof.** (max ≥ min) We prove the theorem by induction on $n + |V|$. For $n = 3$ the result is trivially true. It is also true when $|V| = 1$. In what follows we suppose that $n \geq 4$ and $|V| \geq 2$.

Let $(P, Q)$ be a minimum cover of $(G, V)$ for which $|P| = l$ is as small as possible and subject to this $|Q| = k$ is as large as possible. Note that by the maximality of $k$, for each pair $T \in S_P \cup R_P$, $T \in Q$, (6) because for each $T \in S_P \cup R_P$, $\lceil \frac{r_P(T)}{2} \rceil = 0$.

**Lemma 7** For each $H_i \in Q$, the minimum cover of $(G_P[H_i], H_i)$ is unique and it is the trivial cover.

**Proof.** Let $(P', Q')$ be a minimum cover of $(G_P[H_i], H_i)$. Since the value of the trivial cover of $(G_P[H_i], H_i)$ is $\lceil \frac{r_P(H_i)}{2} \rceil$, $l - l' + \sum_{H_j \in Q'} \lceil \frac{r_P(H'_j)}{2} \rceil = \text{val}(P', Q') \leq \lceil \frac{r_P(H_i)}{2} \rceil$. Using this cover $(P', Q')$, a new cover $(P^*, Q^*)$ of $(G, V)$ can be defined as follows. Let the partition $P^*$ of $V(G)$ be obtained from $P$ by taking the union of all those $V_V$ and $V_H$ whose corresponding vertices in $G_P$ are in the same set of $P'$. Then $l^* = |P^*| = |P'| = l'$. Let $Q^*$ be obtained from $Q$ by deleting $H_i$ and by adding $Q'$. For $H_j \in Q - \{H_i\}$, $r_P(H_j) \leq r_P(H_j)$ by Lemma 3(b). We claim that the new cover is also a minimum cover.

$$\text{val}(P^*, Q^*) = n - l^* + \sum_{H_j \in Q - \{H_i\}} \left[ \frac{r_P(H_j)}{2} \right] + \sum_{H_j \in Q'} \left[ \frac{r_P(H'_j)}{2} \right]$$

$$\leq n - l' + \sum_{H_j \in Q - \{H_i\}} \left[ \frac{r_P(H_j)}{2} \right] + \text{(val}(P', Q') - (l - l'))$$

$$\leq n - l + \sum_{H_j \in Q - \{H_i\}} \left[ \frac{r_P(H_j)}{2} \right] + \left[ \frac{r_P(H'_j)}{2} \right] = \text{val}(P, Q).$$

It follows that equality holds everywhere, so $\text{val}(P', Q') = \lceil \frac{r_P(H_i)}{2} \rceil$, thus the trivial cover of $(G_P[H_i], H_i)$ is a minimum cover. Furthermore, by the minimality of $l$, $|P| \leq |P^*| = |P'| \leq |P|$ that is $P'$ is the trivial partition of $V(G_P[H_i])$ and by the maximality of $k$, $|Q| = |Q^*| = |Q| - 1 + |Q'| \geq |Q|$ that is $|Q'| = 1$, whence the minimum cover of $(G_P[H_i], H_i)$ is unique. □

**Lemma 8** Each component $H_i \in Q$ is critical.

**Proof.** Suppose that there exists a component $H_i \in Q$ for which $(G_P[H_i], H_i)$ is not critical, that is there are two vertices $a$ and $b$ in the same connected component of $G_P[H_i]$ whose identification into a new vertex $v_{ab}$ leaves a $v$-graph $(G', H_i)$ with no perfect $v$-forest. Note that $r_G(E(H_i)) = r_P(H_i) - 1$. By the induction hypothesis, it follows that there is a cover $(P', Q')$ of $(G', H_i)$ so that $\text{val}_G(P', Q') < \frac{r_G(E(H_i))}{2} \leq \lceil \frac{r_P(H_i)}{2} \rceil$. Let $P'' := (P' - X) \cup ((X - v_{ab}) \cup a \cup b)$, where $X$ is the member of $P'$ that contains $v_{ab}$. Then $(P'', Q')$ is a cover of $(G[H_i], H_i)$ and $\text{val}(P'', Q') = \text{val}(P', Q') + 1$. Thus $\text{val}(P'', Q') \leq \lceil \frac{r_P(H_i)}{2} \rceil$. By Lemma 7, $(P'', Q')$ is a minimum cover of $(G_P[H_i], H_i)$ but not the trivial one $(a$ and $b$ are in the same member of $P''$), which contradicts Lemma 7. □
Corollary 9 If $H_i \in Q$ and $a, b \in V(G_P[H_i])$, then there exists an almost perfect v-forest $K$ in $(G_P[H_i], H_i)$ so that $a$ and $b$ belong to different connected components of $K$.

Proof. If $a$ and $b$ are in the same connected component of $G_P[H_i]$, then let $c = a$ and $d = b$, otherwise let $c$ and $d$ be two arbitrary vertices from a connected component of $G_P[H_i]$. By Lemma 8, $H_i$ is critical, so by identifying $c$ and $d$ in $G_P[H_i]$, the v-graph obtained has a perfect v-forest $K'$. Then $K := (V(G_P), E(K'))$ is an almost perfect v-forest in $(G_P[H_i], H_i)$ and $a$ and $b$ belong to different connected components of $K$. □

Remark 2. (a) By Corollary 9, $(G_P[H_i], H_i)$ (and consequently $(G, V)$) contains a v-forest of size $\left\lfloor \frac{r_P(H_i)}{2} \right\rfloor$.
(b) However, at this moment we can not see whether we can choose a v-forest $K_i$ of size $\left\lfloor \frac{r_P(H_i)}{2} \right\rfloor$ for every $H_i \in Q$ so that $\bigcup_{H_i \in Q} K_i$ is a v-forest in $(G, V)$.
(c) Note that by Corollary 9, $r_P(H_i)$ is odd for each component $H_i \in Q$, that is $\left\lfloor \frac{r_P(H_i)}{2} \right\rfloor = \frac{r_P(H_i) - 1}{2}$.

Claim 10 If $l = n - 1$, then $k \geq 2$.

Proof. Suppose $l = n - 1$ and $k = 1$. Then $\text{val}(\mathcal{P}, Q) = n - l + \left\lfloor \frac{r_P(V)}{2} \right\rfloor = 1 + \left\lfloor \frac{r_P(V)}{2} \right\rfloor$. Let $(u_1v_1, u_2v_2)$ be a v-pair in $V$ such that $u_1v_1$ is not a loop. Let us consider the cover $(\mathcal{P}', \mathcal{Q}')$ of $(G, V)$ where each set of $\mathcal{P}'$ contains exactly one vertex of $G$ except one which contains $u_1$ and $v_1$ ($|\mathcal{P}'| = n - 1$) and $\mathcal{Q}'$ contains exactly two members, namely, $H_1' := \{u_1v_1, u_2v_2\}$ and $H_2' := V - H_1'$. (|\mathcal{Q}'| \geq 2 because |V| \geq 2.) Then, $\text{val}(\mathcal{P}', \mathcal{Q}') = n - |\mathcal{P}'| + \left\lfloor \frac{r_P(H_1')}{2} \right\rfloor + \left\lfloor \frac{r_P(H_2')}{2} \right\rfloor = 1 + \left\lfloor \frac{r_P(E(G))}{2} \right\rfloor$. By Lemma 3(c), $r_P(E(G)) \leq 1 + r_P(V)$, so $\text{val}(\mathcal{P}', \mathcal{Q}') \leq \text{val}(\mathcal{P}, \mathcal{Q})$, and hence $(\mathcal{P}', \mathcal{Q}')$ is a minimum cover. This is a contradiction because $|\mathcal{P}'| = n - 1$ and $|\mathcal{Q}'| \geq 2$.

Lemma 11 Let $\mathcal{P}'$ be a refinement of $\mathcal{P}$ and let $H_i \in Q$ be a component for which $H_i \notin \Gamma_D(A_P)$. Then $r_P(H_i) \leq r_P(H_i)$.

Proof. Suppose that $r_P(H_i) > r_P(H_i)$. Let $H = G_P(H_i)$. Then, by applying Lemma 3(d) with $H$ and with $\mathcal{P} / \mathcal{P}'$, suppose that there exists the elementary refinement $\mathcal{P}'$ of $\mathcal{P}$ (say $V_j' \cup V_j'' = V_j$ with $V_j' \in \mathcal{P}', V_j'' \in \mathcal{P}$) so that $\mathcal{P}'$ is a refinement of $\mathcal{P}'$ and $r_P(H_i) > r_P(H_i)$. We shall denote the vertices of $G_P[H_i]$ corresponding to $V_j'$ and $V_j''$ by $v_1$ and $v_2$, respectively. Since $\mathcal{P}'$ is a refinement of $\mathcal{P}'$, $H_i \notin \Gamma_D(A_P)$ implies that $H_i \notin \Gamma_D(A_P)$ that is there exists no augmenting edge for $H_i$ with respect to $\mathcal{P}'$ so $G_P[H_i, H_i]$ has no v-forest of size $\frac{r_P(H_i)}{2}$. By Claim 10, we can use the induction hypothesis (of the theorem), that is there exists a cover $(\mathcal{P}'', \mathcal{Q}'')$ of $(G_P[H_i], H_i)$ so that $\text{val}(\mathcal{P}'', \mathcal{Q}'') \leq \frac{r_P(H_i)}{2} - 1 = \frac{r_P(H_i)}{2} - 1$. Let $\mathcal{P}' := (\mathcal{P}'', A - B) \cup C$, where $A$ and $B \in \mathcal{P}'$ contain $v_1$ and $v_2$ and $C$ is the vertex set of $G_P[H_i]$ corresponding to $A \cup B$. Then $(\mathcal{P}', \mathcal{Q}')$ is a cover of $(G_P[H_i], H_i)$. If $A = B$, then $\text{val}(\mathcal{P}', \mathcal{Q}') = \text{val}(\mathcal{P}'', \mathcal{Q}'') - 1 < \frac{r_P(H_i)}{2} - 1$. This is a contradiction because the minimum cover of $(G_P[H_i], H_i)$ has value $\frac{r_P(H_i)}{2}$ by Lemma 7. Thus $A \neq B$, and in this case $\text{val}(\mathcal{P}', \mathcal{Q}') \leq \text{val}(\mathcal{P}'', \mathcal{Q}'') - 1 < \frac{r_P(H_i)}{2} - 1$. By Lemma 7, $(\mathcal{P}', \mathcal{Q}')$ is a minimum cover of $(G_P[H_i], H_i)$ and in fact it is the trivial cover. Since $A \neq B$ it follows that $(\mathcal{P}', \mathcal{Q}')$ is the trivial cover of $(G_P[H_i], H_i)$ thus $\left\lfloor \frac{r_P(H_i)}{2} \right\rfloor = \text{val}(\mathcal{P}', \mathcal{Q}') \leq \frac{r_P(H_i)}{2} - 1$, so $r_P(H_i) \leq r_P(H_i)$, contradiction. □

Lemma 12 For a refinement $\mathcal{P}'$ of $\mathcal{P}$ (with $l' = |\mathcal{P}'|$ and $l = |\mathcal{P}|$) and for $Q_1 = \Gamma_D(A_P)$, $l' - l \leq |Q_1|$.

Proof. Let $H' := \left( \bigcup_{H_i \in Q_1} H_i \right) \cup R_P$ and let $Q' := (Q - Q_1 - R_P) \cup H'$. We remark that, by Claim 2(b), $r_P(R_P) \leq \sum_{T \in R_P} r_P(T) = \sum_{T \in R_P} 0 = 0$. As $(\mathcal{P}', \mathcal{Q}')$ is a cover of $(G, V)$, $\text{val}(\mathcal{P}, Q) \leq \text{val}(\mathcal{P}', Q')$, that is
\begin{equation}
\begin{aligned}
n - l + \sum_{H_i \in Q_1} \frac{r_P(H_i)}{2} - 1 + \sum_{H_i \in Q - Q_1} \frac{r_P(H_i)}{2} \leq n - l' + \frac{r_P(H')}{2} + \sum_{H_i \in Q - Q_1} \frac{r_P(H_i)}{2}.
\end{aligned}
\end{equation}
By Lemma 11, for $H_i \in Q - Q_1 - R_P$,
\begin{equation}
r_P(H_i) \leq r_P(H_i).
\end{equation}
Let $H := G_P[H']$. By applying Lemma 3(c) with $H$ and $\mathcal{P}'$, and by Claim 2(b),
\begin{equation}
r_P(H') \leq l' - l + r_P(H') \leq l' - l + \sum_{H_i \in Q_1} r_P(H_i) + r_P(R_P) = l' - l + \sum_{H_i \in Q_1} r_P(H_i).
\end{equation}
The equations (7), (8) and (9) imply that

\[
\sum_{H_i \in Q_1} r_p(H_i) - |Q_1| = \sum_{H_i \in Q_1} (r_p(H_i) - 1) \leq 2(l - l') + r_p(H^*) \leq (l - l') + \sum_{H_i \in Q_1} r_p(H_i),
\]

whence \(l' - l \leq |Q_1|\). \(\square\)

**Corollary 13** \(\text{part}(V, E(B)) = \mathcal{P}\).

**Proof.** By definition, there is no edge of \(B\) between two different sets of \(\mathcal{P}\). Let us consider an elementary refinement \(\mathcal{P}'\) of \(\mathcal{P}\). If there was no augmenting edge with respect to \(\mathcal{P}'\), then by Lemma 11, \(\text{val}(\mathcal{P}', Q) = n - |\mathcal{P}'| + \sum_{H_i \in Q} \left(\frac{r_p(H_i)}{2} - 1\right) \leq n - (l + 1) + \sum_{H_i \in Q} \left(\frac{r_p(H_i)}{2}\right) = \text{val}(\mathcal{P}, Q) - 1\), contradicting the minimality of the cover \((\mathcal{P}, Q)\). This implies that for each \(V_j \in \mathcal{P}\), the subgraph of \(B\) spanned on the vertex set \(V_j\) is connected. \(\square\)

Let \(F_i\) be an arbitrary spanning forest of \(G_{\mathcal{P}}[H_i]\) for every component \(H_i \in Q\). Then \(E(F_i) \cap E(F_j) = \emptyset\) if \(i \neq j\) because the components of \(Q\) are disjoint. Let \(W = (V_{\mathcal{P}}, E(W))\) where \(E(W) := \bigcup_{H_i \in Q} E(F_i)\). Then \(\mathcal{P}'\) be a refinement of \(\mathcal{P}\) with \(|\mathcal{P}'| = l'\). Let \(Q_1 := H_{\mathcal{P}}(A_{\mathcal{P}'})\) and \(Q_2 := Q - Q_1\). We define two matroids on \(E(W)\). Let \(\mathcal{G}\) be the cycle matroid of \(W\) with rank function \(r_g\). Let \(\mathcal{F}_{\mathcal{P}'} := F_1 + F_2\) (direct sum), where \(F_j\) will be the following (truncated) partitional matroid (with rank function \(r_j\)) on \(E_j := \bigcup_{H_i \in Q} E(F_i)\) for \(j = 1, 2\). Let \(F_1\) contain those sets \(F \subseteq E_1\) for which \(|F \cap E(F_i)| \leq 1\) for all \(i\) and \(|F| \leq t_0 := |Q_1| = (l' - l)\). Note that \(t_0 \geq 0\) by Lemma 12. Let \(\mathcal{F}_2\) contain those sets \(F \subseteq E_2\) for which \(|F \cap E(F_i)| \leq 1\) for all \(i\). For the rank function \(r'\) of \(\mathcal{F}_{\mathcal{P}'}\), 

\[
r'(X) = \begin{cases} r_1(X \cap E_1) + r_2(X \cap E_2) & \text{if } X \cap E_1 \neq \emptyset \land X \cap E_2 \neq \emptyset, \\ r_1(X \cap E_1) & \text{if } X \cap E_2 = \emptyset, \\ r_2(X \cap E_2) & \text{if } X \cap E_1 = \emptyset. \end{cases}
\]

**Lemma 14** For any refinement \(\mathcal{P}'\) of \(\mathcal{P}\), \(E(W)\) can be written as the union of an independent set in \(\mathcal{G}\) and an independent set in \(\mathcal{F}_{\mathcal{P}'}\).

**Proof.** This is a matroid partition problem. By Nash-Williams’ theorem (see for example [13]) the lemma is true if and only if for any \(Y \subseteq E(W)\), \(|Y| \leq r_g(Y) + r'(Y)\). Suppose that this is not true, and let \(Y\) be a maximum cardinality set violating the above inequality. Then, clearly, \(Y\) is closed in \(\mathcal{F}_{\mathcal{P}'}\). Thus \(Y\) can be written in the form \(Y = \bigcup_{H_i \in Q} E(F_i)\), for some \(Q^* \subseteq Q\). Let \(t := |Q^* \cap Q_1|\). Let \(Q'' := (Q - Q^*) \cup H''\), where \(H'' := \bigcup_{H_i \in Q^*} H_i\). We remark that

\[
r_p(H'') = r_g(Y). \tag{11}
\]

Indeed, for every \(H_i \in Q^*\), \(F_i\) is a spanning forest of \(G_{\mathcal{P}}[H_i]\) hence \(\text{part}(V_{\mathcal{P}}, Y) = \text{part}(V_{\mathcal{P}}, E(H''))\).

**CASE 1.** \(t \leq t_0\). Then \(r'(Y) = |Q^*|\). Since \((\mathcal{P}, Q'')\) is a cover of \((G, V)\), \(0 \leq \text{val}(\mathcal{P}, Q'') - \text{val}(\mathcal{P}, Q) = \left[\frac{r_p(H_i')}{2}\right] - \sum_{H_i \in Q^*} \frac{r_p(H_i)}{2} - 1\), whence, by (11),

\[
|Y| = \sum_{H_i \in Q^*} |E(F_i)| = \sum_{H_i \in Q^*} r_p(H_i) = 2 \sum_{H_i \in Q^*} \frac{r_p(H_i)}{2} - 1 + |Q^*| \leq 2 \frac{r_p(H'')}{2} + |Q^*| = r_g(Y) + r'(Y),
\]

contradicting the assumption for \(Y\).

**CASE 2.** \(t > t_0\). Now, by the closedness of \(Y\) in \(\mathcal{F}_{\mathcal{P}'}\), \(Y\) contains all the forest \(F_i\) for which \(H_i \in Q_1\). Thus \(r'(Y) = r_1(Y \cap E_1) + r_2(Y \cap E_2) = t_0 + (|Q^*| - |Q_1|) = |Q^*| - (l' - l)\). Let us consider the following cover \((\mathcal{P}', Q^3)\) of \((G, V)\), where \(Q^3 := (Q'' - H'' - (\mathcal{V}_{\mathcal{P}'} \cap \mathcal{R}_{\mathcal{P}})) \cup H^3\) where \(H^3 := (H'' \cup (\mathcal{V}_{\mathcal{P}'} \cap \mathcal{R}_{\mathcal{P}}))\). Note that \(\text{val}(\mathcal{P}_{\mathcal{P}'}, \mathcal{R}_{\mathcal{P}}) = 0\). By Lemma 3(c), Claim 2(b) and (11), \(r_p(H^3) \leq l' - l + r_p(H^3) \leq l' - l + r_p(H'') + r_p(\mathcal{V}_{\mathcal{P}'}, \mathcal{R}_{\mathcal{P}}) = l' + r_g(Y)\). By Lemma 11,

\[
\text{val}(\mathcal{P}', Q^3) = n - l' + \left[\frac{r_p(H^3)}{2}\right] + \sum_{H_i \in Q^3} \left[\frac{r_p(H_i)}{2}\right] \leq n - l' + \frac{l' - l + r_g(Y)}{2} + \sum_{H_i \in Q^3} \left[\frac{r_p(H_i)}{2}\right].
\]

Then \(0 \leq \text{val}(\mathcal{P}', Q^3) - \text{val}(\mathcal{P}, Q) \leq l' - l' + l' + r_g(Y) - \sum_{H_i \in Q} \frac{r_p(H_i)}{2} - 1\) implies that

\[
|Y| = \sum_{H_i \in Q} |E(F_i)| = \sum_{H_i \in Q} r_p(H_i) = 2 \sum_{H_i \in Q} \frac{r_p(H_i)}{2} - 1 + |Q^*| \leq r_g(Y) + |Q^*| - (l' - l) = r_g(Y) + r'(Y),
\]

contradicting the assumption for \(Y\). The proof of Lemma 14 is complete. \(\square\)
Corollary 15  (a) There exists a forest $F$ in the graph $W$ so that for $n-l$ indices $i$, $E(F_i) \subseteq E(F)$ and $E(F) \cap E(F_i)$ is an almost spanning forest of $V(G_{P[H_i]})$ for the other indices.
(b) Therefore there exists a forest $F' \subseteq F$ in $W$ so that $E(F') \cap E(F_i)$ is an almost spanning forest of $V(G_{P[H_i]})$ for every $H_i \in Q$.

Proof.  (a) By Lemma 14, for the trivial partition $P'$ of $V(G)$, there exist $F, L \subseteq E(W)$ such that $E(W) = F \cup L$, $F$ is a forest of $W$, $|L \cap E(F_i)| \leq 1$ for all $i$, and, by Lemma 12, for at least $n-l$ components $H_i \in Q_1$, $|L \cap E(F_i)| = 0$. Then $F$ is the desired forest.
(b) is implied by (a).

Remark 3. By Corollary 15(b), there exists a forest $F$ in $W$ (and consequently in $G_P$) so that $E(F) \cap E(F_i)$ is an almost spanning forest of $G_{P[H_i]}$ for all components $H_i$. Let $H_i$ be an arbitrary component of $Q$. By Corollary 9, for the two vertices $a$ and $b$ defined in Claim 4(b), there exists an almost perfect v-forest $K$ in $(G_{P[H_i]}, H_i)$ so that $a$ and $b$ belong to different components of $K$. Then, by Claim 4(b), $(G_P \setminus E(F_i)) \cup E(K)$ is a forest of $G_P$. We can do this for all components, so the v-graph $(G_P, V)$ (and hence $(G, V)$) contains a v-forest of v-size $\sum_{H_i \in Q} \binom{r_i}{2}$.

Now we define a matroid $M$ on the components of $Q$. Let $Q' \subseteq Q$ be an independent set in $M$, that is $Q' \in I(M)$ if and only if there is $f_i \in E(F_i)$ for each component $H_i \in Q-Q'$ so that $E(W) - \{f_i : H_i \in Q-Q'\}$ is a forest in $W$.

Lemma 16  $M$ is a matroid.

Proof.  We show that $M$ satisfies the three properties of independent sets of matroids.
(1) By Corollary 15(b), $0 \in I(M)$.
(2) If $Q'' \subseteq Q' \subseteq I(M)$, then $Q'' \in I(M)$ because any subgraph of a forest is a forest.
(3) Let $Q', Q'' \in I(M)$ with $|Q''| < |Q'|$. By definition, there are $f_i' \in E(F_i)$ for $H_i \in Q-Q'$ and $f_i'' \in E(F_i)$ for $H_i \in Q-Q''$ so that $T' := E(W) - \{f_i' : H_i \in Q-Q'\}$ and $T'' := E(W) - \{f_i'' : H_i \in Q-Q''\}$ are forests in $W$. Choose these two forests $T'$ and $T''$ so that $|T' \cap T''|$ is as large as possible. $T'$ and $T''$ are two independent sets in the matroid $Q$ and $|Q''| < |Q'|$ implies that $|T''| < |T'|$ thus there is an edge $e \in T'-T''$ so that $T'' \cup e$ is also a forest in $W$. Then $e = f''_j$ for some $j$. If $H_j \notin Q'$ then $f''_j \notin T'$, then $T'' := T'' + f''_j - f'_j$ is a forest and $|T' \cap T''| > |T' \cap T''|$, contradiction. Thus $H_j \notin Q' - Q''$ and $Q'' \cup \{H_j\} \in I(M)$ and we are done.

We shall apply the matroid intersection theorem of Edmonds [4] for the following two matroids on the edge set of the graph $D$ introduced in Section 2. For a set $Z \subseteq E(D)$, let us denote by $Z_1$ and $Z_2$ the sets of end vertices of $Z$ in the colour classes $E(B)$ and $Q$. The rank of $Z$ in the first matroid will be $r_B(Z_1)$ and $r_M(Z_2)$ in the second matroid, where $r_B$ is the rank function of the cycle matroid of the graph $B$ and $r_M$ is the rank function of the above defined matroid $M$. Note that if a vertex $x$ is in the colour class $E(B)$ (in $Q$) then the edges incident to $x$ correspond to parallel elements of the first (second) matroid.

Remark 4. By Corollary 13, $r_B(E(B)) = n-l$ and by Corollary 15(a), $r_M(Q) \geq n-l$. Moreover, if $P'$ is a refinement of $P$, then by Lemma 12 and Lemma 14,

$$l' - l \leq r_M(\Gamma_D(A_{P'})).$$  \hspace{1cm} (12)

Lemma 17  There exists a common independent set of size $n-l$ of the above defined two matroids.

Proof.  By the matroid intersection theorem of Edmonds [4], we have to prove that

$$n-l \leq r_B(E(D) - Z) + r_M(Z) \quad \text{for all } Z \subseteq E(D).$$  \hspace{1cm} (13)

Suppose that there is a set $Z$ violating (13). We may assume that $E(D) - Z$ is closed in the first matroid. This implies that there is a set $J \subseteq E(B)$ so that $E(D) - Z$ is the set of all edges of $D$ incident to $J$ and $J$ is closed in the cycle matroid of $B$. Then by the closedness of $J$, $E(B) - J$ is the set of augmenting edges of the refinement $P' := \text{part}(V_{P'}, J)$ of $P$, that is, $A_{P'} = E(B) - J$. (Obviously, $Z$ is the set of all edges incident to $E(B) - J$ in $D$.) Then $r_M(Z) = r_M(\Gamma_D(A_{P'}))$ and $r_B(E(D) - Z) = r_B(J) = n-l'$, where $l' = \lvert P' \rvert$. By
of the above two matroids. (By Lemma 17, such a set exists.) It follows that it covers a basis $B'$ in the cycle matroid of $B$ and an independent set $Q'$ in $M$ with $|Q'| = n - l$. Thus there exists a forest $F'$ of $G_P$ so that it is the union of the spanning forests $F_i$ in $G_P[H_i]$ for $H_i \in Q'$ and the almost spanning forests $F_i - f_i$ in $G_P[H_i]$ (for appropriate $f_i$) for $H_i \in Q - Q'$. By Lemma 3(a), $E' \cup E(F')$ is a forest on $V(G)$ and it contains $2(n - l + \sum_{H_i \in Q} \lfloor \frac{r_P(H_i)}{2} \rfloor)$ edges. Indeed, $|E' \cup E(F')| = |E'| + |E(F')| = n - l + \sum_{H_i \in Q} r_P(H_i) + \sum_{H_i \in Q-Q'} r_P(H_i) - 1 = n - l + \sum_{H_i \in Q-Q'} (r_P(H_i) - 1) = 2(n - l + \sum_{H_i \in Q} \lfloor \frac{r_P(H_i)}{2} \rfloor)$.

We shall change the forests by appropriate ones obtaining a $v$-forest of the desired size. As in Remark 3, for each $H_i \in Q - Q'$ we may replace $F_i - f_i$ in $F'$ by an almost perfect $v$-forest of $(G_P[H_i], H_i)$ obtaining a forest $F''$ on $V_P$ with the same number of edges. As above, $E' \cup E(F'')$ is a forest on $V(G)$. For all $e \in E'$, $e$ is an augmenting edge for $H_e \in Q'$, where $H_e$ is the pair of $e$ in the matching $N$. Thus there exists a $v$-forest $K_e$ in $(G_P[H_v], H_v)$ of size $\frac{r_P(H_v)}{2}$ so that the trace of $K_e$ in $V_i$ is the edge $e$, where $V_i \in \mathcal{P}$ contains the edge $e$. (Note that each $K_e$ corresponds to a graph $F_e'$ in $G_P[H_e]$ such that $part(V_P, F_e') = part(V_P, F_e)$.) Replace $E' \cup \cup_{H_i \in Q} E(F_i)$ by $\cup_{e \in E'} E(K_e)$. By Lemma 5 with $F = F' \cup E(F''), F_0 = F$, $F_1 = F$, $F'_1 = K_e$ (note that all the conditions of Lemma 5 are satisfied), we obtain again a forest of $G$ with the same number of edges. The forest obtained consists of $v$-pairs, that is it is a $v$-forest of size $n - l + \sum_{H_i \in Q} \lfloor \frac{r_P(H_i)}{2} \rfloor$. \hfill \Box

Acknowledgments

I am very grateful to Gábor Bacsó for the fruitful discussions on the topic. I thank Stanislas Francfort for the very careful reading of the paper.
