ABSTRACT

Sphingosine-1-phosphate (S1P) receptor agonists are novel immunosuppressive agents. The selectivity of S1P₁ against S1P₃ is strongly correlated with lymphocyte sequestration and minimum acute toxicity and bradycardia. This study describes molecular modeling, site-directed mutagenesis, and affinity studies exploring the molecular basis for selectivity between S1P₁ and S1P₃ receptors. Computational models of human S1P₁ and S1P₃ receptors bound with two nonselective agonists or two S1P₁-selective agonists were developed based on the X-ray crystal structure of bovine rhodopsin. The models predict that S1P₁ Leu276 and S1P₃ Phe263 contribute to the S1P₁/S1P₃ selectivity of the two S1P₁-selective agonists.

These residues were subjected to site-directed mutagenesis. The wild-type and mutant S1P receptors were expressed in Chinese hamster ovary cells and examined for their abilities to bind to and be activated by agonists in vitro. The results indicate that the mutations have minimal effects on the activities of the two nonselective agonists, although they have dramatic effects on the S1P₁-selective agonists. These studies provide a fundamental understanding of how these two receptor-selective agonists bind to the S1P₁ and S1P₃ receptors, which should aid development of more selective S1P₁ receptor agonists with immunosuppressive properties and improved safety profiles.

Sphingosine-1-phosphate (S1P) and lysophosphatidic acid (LPA) are important signaling molecules that activate a family of related G protein-coupled receptors (GPCRs) called endothelial differentiation gene (Edg) receptors (Chun et al., 2002). The receptors S1P₁ (Edg1), S1P₂ (Edg5), S1P₃ (Edg3), S1P₄ (Edg6), and S1P₅ (Edg8) bind S1P and regulate many cellular functions, including cell growth, proliferation, apoptosis, adhesion, and differentiation (Pyne and Pyne, 2000; Spiegel and Milstien, 2003). A role for S1P receptors in reg-

ulating immune function was discovered when the mechanism of FTY720 (Fig. 1) was elucidated. FTY720 is in clinical trials to prevent transplant rejection (Kiuchi et al., 2000) and is metabolized rapidly in the blood to the corresponding phosphate ester, FTY720-P (Fig. 1), which is a full agonist of S1P₁, S1P₃, S1P₄, and S1P₅ (Mandala et al., 2002). FTY720 causes immunosuppression by depleting peripheral blood lymphocytes, sequestering them in secondary lymphoid organs (Chiba et al., 1998) and preventing effector lymphocyte egress from draining lymph nodes to lymph and the blood compartment (Xie et al., 2003). FTY720 also has pleiotropic cardiovascular effects. In stable renal transplant patients, it causes a dose-dependent transient bradycardia (Budde et al., 2003) and, in anesthetized rats, either decreases or increases mean arterial pressure depending on the dose (Tawadrous et al., 2002).

ABBREVIATIONS: S1P, sphingosine-1-phosphate; LPA, lysophosphatidic acid; GPCR, G protein-coupled receptor; Edg, endothelial differentiation gene; TM, transmembrane helix; FTY720, 2-amino-2-[2-(4-octylphenyl)ethyl]propane-1,3-diol; FTY720-P, 2-amino-2-(hydroxymethyl)-4-(4-octylphenyl)butyl dihydrogen phosphate; compound A, 1-(3-methyl-4-[[4-phenyl-5-(trifluoromethyl)-2 thienyl]methoxy]benzyl)azetidone-3-carboxylic acid; compound B, 1-[4-[5-(4-isobutylphenyl)-1,2,4-oxadiazol-3-yl]benzyl]azetidone-3-carboxylic acid; CHO, Chinese hamster ovary; MMFF, Merck molecular force field; PCR, polymerase chain reaction; HT, hypoxanthine/thymidine; PDB, Protein Data Bank; TM, transmembrane; PBS, phosphate-buffered saline; GTP_γS, guanosine 5'-O-(3-thio)triphosphate; FACS, fluorescence-activated cell sorting.

Studies on several S1P receptor agonists with varying degrees of selectivity (Hale et al., 2004a; Li et al., 2005) indicate that S1P₁ receptor agonism is strongly correlated with lymphocyte sequestration, whereas S1P₃ receptor agonism is associated with acute toxicity and bradycardia in rodents (Forrest et al., 2004; Sanna et al., 2004). For example, S1P₁-selective compounds A and B (Fig. 1) effectively alter lymphocyte trafficking and have much less potential to cause bradycardia and hypertension (Hale et al., 2004a; Li et al., 2005). The toxicity and bradycardia associated with the non-selective agonists S1P and FTY720-P were also abrogated in S1P₃ ^{-/-} mice confirming that S1P₃ agonism mediates these toxicities (Forrest et al., 2004; Sanna et al., 2004). These findings led us to study how S1P₁-selective agonists bind to S1P₁ and S1P₃.

GPCRs share a common 3D topology, consisting of seven *trans*-membrane helices (TMs) connected by three extracellular and three intracellular loops (van Rhee and Jacobson, 1996; Bosch et al., 2005; Fanelli and De Benedetti, 2005). S1P receptors belong to the largest subfamily A of GPCRs, which includes rhodopsin (for which high resolution X-ray crystal structures are available) (Palczewski et al., 2000; Teller et al., 2001; Okada et al., 2002; Edwards et al., 2004; Okada et al., 2004). Although the rhodopsin molecules are in the unactivated "dark state" in the structures, they provide attractive templates for homology modeling of family A GPCRs (Meng and Bourne, 2001; Archer et al., 2003; Bosch et al., 2005; Fanelli and De Benedetti, 2005).² Parrill and colleagues proposed homology models for S1P₁ and S1P₄ receptors bound to natural ligands and agonists based on a theoretically calculated rhodopsin model (Parrill et al., 2000; Inagaki et al., 2005; Jo et al., 2005). In their models, charged Arg and Glu residues at positions 3.28 and 3.29 on TM3 of S1P₁ and S1P₄ interact with the phosphate and ammonium moieties of the natural ligand S1P, respectively.

We describe molecular models of the S1P₁ and S1P₃ receptors bound to nonselective compounds S1P, FTY720-P, or S1P₁-selective compounds A or B based on the X-ray crystal structure of bovine rhodopsin (Palczewski et al., 2000). Energy-minimized conformations of agonists were docked into the proposed S1P₁ binding pocket. Two groups of residues were identified based on the nature of their interactions with the docked agonists. The first consists of Arg120(3.28) and Glu121(3.29), identified previously (Parrill et al., 2000; Inagaki et al., 2005; Jo et al., 2005). The second group consists of aromatic and hydrophobic residues on TM3, -5, and -6 that we propose form a hydrophobic binding pocket that interacts with the lipophilic chains of the agonists. One S1P₁ residue in this second group, Leu276(6.55), is not conserved in S1P₃, and our models predict that it contributes to the S1P₁ selectivity of compounds A and B. This S1P₁ residue and the corresponding Phe263 in S1P₃ were subjected to site-directed mutagenesis. The mutant and wild-type S1P receptors were

expressed in Chinese hamster ovary (CHO) cells and examined for their abilities to bind to and be activated by agonists *in vitro*. Results from these experiments confirmed the predictions of our computational models and begin to provide an understanding of how compounds A and B bind S1P₁ selectively.

Materials and Methods

Sequence Alignment of S1P Receptors with Bovine Rhodopsin. The nomenclature proposed by van Rhee and Jacobson (1996) is used to describe the amino acid residues in the S1P receptors. Each residue is represented in two parts. The first part consists of the name and sequential number of an amino acid in a given S1P receptor sequence and is followed by a parenthesis with the second part, which is the index number defined by Ballesteros and Weinstein (1995). In the Ballesteros-Weinstein system, each residue identifier begins with the TM number (e.g., 3 for TM3) followed by the position in the helix relative to the most highly conserved residue that is assigned number 50. For example, the charged residue pair in TM3 is represented as 3.28 and 3.29 [i.e., Arg120(3.28) and Glu121(3.29) in S1P₁ and Arg114(3.28) and Glu115(3.29) in S1P₃].

Multiple sequence alignments of bovine rhodopsin, five human S1P receptors, three closely related human LPA receptors, and some selected GPCR subfamily A sequences were generated with the program ClustalW (Thompson et al., 1994). After computational alignment, manual adjustments were made to eliminate gaps in the TM regions.

Three-Dimensional Modeling of the S1P₁ Receptor. The homology model of S1P₁ was generated with the program Quanta/Modeler (Accelrys Software Inc., San Diego, CA) based on the X-ray crystal structure of bovine rhodopsin [Protein Data Bank (PDB) entry 1F88] (Palczewski et al., 2000). The amino-terminal 41 resi-

Fig. 1. The chemical structures of S1P, FTY720, FTY720-P, and compounds A and B.

² After the manuscript for this article was submitted, we noted the recent release of X-ray crystal structures of activated forms of rhodopsin, including bathorhodopsin (PDB entry 2G87) (Nakamichi and Okada, 2006a), lumirhodopsin (PDB entry 2HPY) (Nakamichi and Okada, 2006b), and a photoactivated deprotonated intermediate of rhodopsin (PDB entry 2I37) (Salom et al., 2006). Given the high structural similarities between bovine rhodopsin in the dark state and the activated forms, the use of the dark state rhodopsin (PDB entry 1F88) as a modeling template would seem to be a reasonable starting point for homology modeling of family A GPCRs bound to agonists and antagonists.

dues and carboxyl-terminal 51 residues of rhodopsin were excluded because of the lack of available template for these regions. The homology model was further refined using the Molecular Mechanics and Molecular Dynamics optimization to release the strain. The quality of the homology model was checked by Protein Health in Quanta (Accelrys Software Inc.). The S1P₃ homology model was constructed in a similar fashion. Because S1P₁ and S1P₃ receptors share high sequence identity and similarity, and the models were constructed using the same rhodopsin template, the models have very similar topologies with a root-mean-square deviation less than 1 Å for the receptor backbones. To minimize potential uncertainties introduced in modeling the flexible amino acid side chain structures, the S1P₁ homology model was used to dock agonists. The S1P₃ receptor was modeled based on the S1P₁ homology model by mutating the nonconserved residues. This minimizes potential artifacts from the homology modeling but retains the appropriate level of detail needed to select residues of interest identified through the docking studies.

Agonist Docking in the S1P₁ Receptor. The *S*-enantiomer of FTY720-P is its most potent enantiomer (Hale et al., 2004b) and was initially used in docking experiments because the affinities of the S1P enantiomers were unknown when these experiments were initiated. One hundred FTY720-P conformations were generated using our implementation of the distance geometry approach, which incorporates the theory and algorithm as described previously (Crippen and Havel, 1988). The conformer set was energy minimized using a distance-dependent dielectric of 2*r* with the MMFF's force field (Halgren, 1996). Manual docking placed the anionic phosphate and the positively charged ammonium of groups of FTY720-P close to the Arg120(3.28) and Glu121(3.29) on TM3. This docking placed the lipophilic chain of FTY720-P in a location similar to retinal in the rhodopsin-retinal complex. Because S1P and rhodopsin belong to GPCR subfamily A and the S1P receptor models were generated from and are similar to the rhodopsin crystal structure, the models place the lipophilic chains of FTY720-P in a hydrophobic pocket that is similar to that occupied by retinal between TM3, -5, -6, and -7. Ligand binding pockets lie between TM3, -5, -6, and -7 in many GPCRs, and this is considered a common feature for family A GPCRs (Bondensgaard et al., 2004). Docking models of the S1P₁ receptor with FTY720-P were obtained in a stepwise fashion to obtain the best docking pose and to minimize potential biases introduced by the initially manual docking of FTY720-P in the S1P₁ model. First, the hundred conformers of FTY720-P were docked into the putative binding pocket with their lipophilic chain superimposed onto the retinal structure by SQ calculations (Miller et al., 1999). The receptor complexes were energy optimized by MMFF's force field with the agonists fully optimized inside the binding pocket, which allowed some degree of flexibility. The side chains of residues with any atom located within 5 Å of the agonists were fully minimized in conjunction with the agonists. Residues falling within 5 to 10 Å of the agonists were included in the calculations as rigid elements, and the residues beyond a 10-Å cutoff from the agonist were ignored in the calculations. The total energy of the complex, the individual energies of the agonist and the receptor, and the interaction energy between the agonist and the receptor were calculated. The best docking mode was determined by selecting those poses with the most stabilizing interaction energy and minimal amount of strain on the agonist and by visual inspection of the interactions. This receptor-agonist model was used as a second template to superpose another hundred conformers, followed by the same procedure of energy optimization of complexes. The cycles continued until the docking pose could not be improved energetically. The docking models of S1P₁ receptor with S1P₁ compounds A and B, were derived from the final docking model of S1P₁ receptor with FTY720-P, through similar cycles of conformational searches and energy minimizations, superposition onto the template, energy optimizations of complexes, and determinations of best docking poses by energy and visual check of interactions. Other docking programs, such as ICM (Molsoft LLC, San Diego, CA), were

used to generate FTY720-P docking poses in the S1P₁ receptor but did not generate more energetically favorable or new models.

Synthesis. The syntheses of compounds A and B have been described previously (Hale et al., 2004a; Li et al., 2005). All compounds were characterized by ¹H NMR, mass spectrometry, and high-performance liquid chromatography and were judged to be >95% pure.

Cloning the Human S1P₁ and S1P₃ Receptors into Expression Plasmids. An N-terminal Flag-tagged human S1P₃ receptor sequence was amplified from an expression vector provided by Kevin Lynch (University of Virginia, Charlottesville, VA) by PCR amplification using the primer set SAP470 (5'-GAATTCGCCACCATGGATTACAAGGATGACG-3') and SAP471 (5'-GCGGCCGCTCAGTTGCA-GAAGATCCCATT-3'), which introduced a Kozak sequence, as well as EcoRI and NotI sites at the 5' and 3' termini, respectively. The accession number of the sequence of the human S1P₃ in this study is X83864, and the N-terminal Flag sequence (amino acids MDYKDDDDKSPGGG) replaces the initiator methionine codon of the human S1P₃ sequence. The PCR product was cloned into pCR4.0-TOPO (Invitrogen, Carlsbad, CA) and confirmed by DNA sequence analysis. The resulting plasmid, pJAC145, was digested with EcoRI and NotI, and the S1P₃ fragment was subcloned into compatible sites of pBlue-script-KS II+ (Stratagene, La Jolla, CA) and the mammalian expression vector pCDEF3neo (Goldman et al., 1996), which contains the human EF-1a promoter. The resulting plasmids, pJAC149 and pJAC147-9, were confirmed by DNA sequence analysis.

An N-terminal Flag-tagged human S1P₁ receptor sequence was cloned from an expression plasmid provided by Kevin Lynch by PCR amplification using the primer set SAP468 (5'-GGATCCGCCAC-CATGGACTACAAGGACGACG-3') and SAP469 (5'-GCGGCCGC-CTAGGAAGAAGAGTTGACGTTTC-3'), which introduced a Kozak sequence as well as BamHI and NotI sites at the 5' and 3' termini, respectively. The accession number of the sequence of the human S1P₁ in this study is AF233365, and the N-terminal Flag sequence (amino acids MDYKDDDDKLEL) replaces the initiator methionine codon of the human S1P₁ sequence. The PCR product was cloned into pCR4.0-TOPO and confirmed by DNA sequence analysis. The resulting plasmid, pGC106-26, was digested with BamHI and NotI, and the S1P₁ fragment was subcloned into compatible sites of pBlue-script-KS II+ and the mammalian expression vector pCDEF3neo (Goldman et al., 1996) to yield pGC109 and pGC108-C2, respectively. The sequences of the inserts in these plasmids were confirmed by DNA sequence analysis.

Site-Directed Mutagenesis of S1P₁ and S1P₃ Receptors. The S1P₁ Leu276Phe and S1P₃ Phe263Leu mutations were created in pGC109 and pJAC149, respectively, using the Transformer site-directed mutagenesis kit (Clontech, Mountain View, CA) and the manufacturer's recommended protocols. The mutagenic and selection primers and restriction enzyme used to generate the S1P₁ mutation were SAP486 (5'-phosphate-CTCTTCATCCTGTTCTGCTGGATGTG-3'), SAP505 (5'-phosphate-ATCCCGTATTGATCCGGCAAGAGC-3'), and BsaHI, respectively. The mutagenic and selection primers and restriction enzyme used to generate the S1P₃ mutation were SAP486 (5'-phosphate-CTCTTCATCCTGTTCTGCTGGATGTG-3'), SAP506 (5'-phosphate-GACTGGTGAGTAT-TCAACCAAGTCATT-3'), and ScaI, respectively. The coding sequences of the S1P₁ Leu276Phe and S1P₃ Phe263Leu mutants were confirmed by DNA sequence analysis. For expression studies, the S1P₁ Leu276Phe mutant was cloned into pCDEF3neo as a BamHI-NotI fragment. The S1P₃ Phe263Leu mutant was subcloned into the EcoRI-NotI restriction sites of vector pCDEF3neo.

Transient Expression of the S1P₁ and S1P₃ Receptors. For expression studies with the S1P₃ receptor, CHO cells were plated at a density of 1.6×10^6 cells per 100-mm culture dish. After 24 h of incubation at 37°C, cells were transfected with 2 μg of S1P₃ plasmid DNA and 100 μg of Lipofectamine transfection reagent (Invitrogen) in serum-free Iscove's modified Dulbecco's medium (Invitrogen) supplemented with 1 mM sodium pyruvate and HT (0.1 mM sodium hypoxanthine and 16 μM thymidine) (Invitrogen) for 5 h at 37°C, per

the manufacturer's protocol. The transfection reaction was removed from the cell monolayer and replaced with Iscove's modified Dulbecco's medium containing sodium pyruvate, HT, and 10% charcoal/dextran-treated fetal bovine serum (Hyclone, Logan, UH). Transfected cells were allowed to recover for approximately 18 h at 37°C. Transient transfection experiments with the S1P₁ receptor were carried out in a similar manner with 8 μg of plasmid DNA.

Production of Stable Cell Lines Expressing S1P Receptors. CHO cells were transfected with plasmids encoding the S1P₁ and S1P₃ wild-type or mutant receptors, and clonal cell lines stably expressing the receptors were isolated in Iscove's modified Dulbecco's medium supplemented with sodium pyruvate, HT, 10% charcoal/dextran-treated fetal bovine serum after selection with G418. Stable CHO cell lines expressing the S1P₁ and S1P₃ receptors were identified in [³³P]S1P binding assays using whole cells and assay conditions described below.

Preparation of Membranes from Whole Cells. Cell membranes were prepared from whole cells, as described previously (Mandala et al., 2002). Protein concentrations were determined using the Bradford protein assay kit II (Bio-Rad Laboratories, Hercules, CA).

Competitive Ligand Binding Assays. Transiently transfected CHO cells expressing the S1P receptors were assayed for binding of [³³P]S1P (3000 Ci/mmol) using published procedures (Mandala et al., 2002), modified as follows. Transfected cells were dissociated from monolayer cultures in enzyme-free cell dissociation buffer (Specialty Media, Phillipsburg, NJ), collected by centrifugation at 400g, washed once with PBS, and resuspended in binding buffer (50 mM HEPES, 5 mM MgCl₂, 1 mM CaCl₂, 0.5% bovine serum albumin, and 1 mM sodium vanadate) at a concentration of 2.5 × 10⁵ cells/ml. The binding reactions with whole cells were initiated by the addition of 100 μl of transfected cells (2.5 × 10⁴) to 100 μl of 0.1 nM [³³P]S1P/unlabeled S1P ligand in 96-well multiscreen filtration plates (Millipore, Bedford, MA). The reactions were incubated at 22°C for 1 h. After ligand binding, the reactions were washed twice with 150 μl of unlabeled binding buffer, the assay plate was dried, and 100 μl of Microscint 20 (PerkinElmer Life and Analytical Sciences, Boston, MA) was added to each well. Plates were counted in a PerkinElmer Life and Analytical Sciences Microplate scintillation and luminescence counter or the Wallac Trilux 1450 Microbeta liquid scintillation and luminescence counter (PerkinElmer Life and Analytical Sciences). Competitive ligand binding assays with membranes prepared from stably transfected CHO cells and 0.1 nM [³³P]S1P/unlabeled S1P ligand were performed as described previously (Mandala et al., 2002). Assays of the S1P₃ receptors were performed with 0.25 μg of membrane protein. Western hybridization (see Fig. 6 under *Results*) and radioligand binding experiments titrating membrane protein concentration (data not shown) indicated that the S1P₁ Leu276Phe receptor was expressed at a higher density than the wild-type receptor in the stable CHO cell lines. Competition binding assays of the S1P₁ wild-type and S1P₁ Leu276Phe receptors were performed with 0.57 and 0.285 μg, respectively. Binding experiments were performed in triplicate in three separate experiments. Data were analyzed by nonlinear regression using a one-site competition model in the program Prism (GraphPad Software, San Diego, CA) to determine Log IC₅₀. The Log IC₅₀ values from each experiment were analyzed in an unpaired Student's *t* test.

S1P Saturation Binding Assays. The K_d and B_{max} values of mutant and wild-type receptors in membrane fractions from the stable CHO cell lines expressing the S1P₁ or S1P₃ receptors were determined in saturation binding assays with [³³P]S1P (3000 Ci/mmol) in two experiments performed in triplicate. A cocktail of unlabeled S1P and [³³P]S1P ligand was titrated in triplicate in a six-point titration, ranging from 3 nM S1P to 0.025 nM in binding buffer. In prewetted 96-well multiscreen filtration plates (Millipore, Medford, MA), 100 μl of each ligand dilution was added to each reaction well. Two microliters of 50 μM unlabeled S1P was added to a parallel set of reactions to determine nonspecific binding. Reac-

tions were initiated by the addition of membrane fractions, incubated at 22°C for 1 h, and washed twice with 150 μl of chilled binding buffer. After drying assay plates at 40°C for 1 h, 100 μl of Microscint 20 (PerkinElmer Life and Analytical Sciences) was added to each well and the plates were counted in a Wallac Trilux 1450 Microbeta liquid scintillation and luminescence counter (PerkinElmer Life and Analytical Sciences). Data were analyzed by nonlinear regression and fit to a one-site binding model using the program Prism to determine the K_d and B_{max} values (GraphPad Software).

Measurements of [³⁵S]GTPγS Binding. [³⁵S]GTPγS (1250 Ci/mmol) binding was assayed in membranes (3 μg) prepared from CHO cell lines as described previously (Mandala et al., 2002). The reactions were incubated at 22°C for 1 h and washed six times with distilled water using a Filtermate Harvester (PerkinElmer Life and Analytical Sciences). After drying the reaction plates at 50°C, 50 μl of ScintiSafe Plus 50% (Fisher Scientific Co., Pittsburgh, PA) was added to each well, and the plates were counted in a Microplate scintillation and luminescence counter or a Wallac Trilux 1450 Microbeta liquid scintillation and luminescence counter. [³⁵S]GTPγS binding assays were performed in triplicate in three separate experiments. Data were analyzed by nonlinear regression and fit to a sigmoidal dose-response curve using the program Prism (GraphPad Software) to determine the Log EC₅₀ values. The Log EC₅₀ values of individual compounds for the wild-type and mutant receptors were analyzed in an unpaired Student's *t* test. The efficacies (E_{max}) of the agonists tested to stimulate [³⁵S]GTPγS binding were calculated as the percentage of the maximal increase obtained using 5 μM S1P on the wild-type S1P₁ or S1P₃ receptors.

S1P₁ and S1P₃ Antisera. The C-terminal S1P₁ rabbit antiserum MS1766 has been described previously (Forrest et al., 2004). A peptide in the N terminus of human S1P₃ (REHYQYVVGKLAGRLK-EASE) was synthesized (SynPep Corp, Dublin, CA), conjugated to keyhole limpet hemocyanin, and used to immunize rabbits (Covance Research Products, Denver, PA). Specific IgG fractions were affinity purified using the immunizing peptide and tested by Western hybridization against a panel of human, mouse, and rat S1P receptors. The S1P₃ antiserum MS2284 was specific for the human S1P₃ receptor.

Confocal Microscopy Studies of S1P₁ and S1P₃ Receptor Expression. Stable CHO clones expressing the receptors were plated in four chambers of the Lab-Tek II Chamber 1.5 German Coverglass System at a density of 40,000 cells per chamber, in Iscove's modified Dulbecco's medium with sodium pyruvate, HT, 10% charcoal/dextran-treated fetal bovine serum, and 25 mM HEPES buffer, pH 7.5. Cells were allowed to adhere for 24 h at 37°C. Growth medium was removed and cells were washed/equilibrated with FACS buffer (1× PBS containing 2.5% charcoal/dextran-treated fetal bovine serum, 25 mM HEPES, and 0.05% NaN₃). To detect S1P₃, adherent cells were blocked with goat IgG blocking antibody (MP Biomedicals, Irvine, CA) at 100 μg/ml in FACS buffer. After 10 min of incubation at 22°C, cells were incubated with receptor-specific antisera, including a rabbit S1P₁ antiserum (MS1766) or a rabbit S1P₃ antiserum (MS2284) at 100 μg/ml in a 200-μl reaction volume. A normal rabbit anti-IgG antibody (Santa Cruz Biotechnology, Santa Cruz, CA) served as the isotype control. In addition, the fourth chamber of cells did not receive antibody and served as the nonspecific fluorescence control. Cells were incubated for 30 min at 22°C, followed by 2 washes with FACS buffer. Cells were then incubated with a secondary goat anti-rabbit IgG fluorescein isothiocyanate-labeled antibody (Santa Cruz Biotechnology) at 25 μg/ml for 30 min at 22°C. Cells were washed two times with FACS buffer, fixed with BD Cytotfix/Cytoperm solution (BD Biosciences Pharmingen, San Diego, CA), and washed with BD Perm/Wash solution (BD Biosciences Pharmingen) that was diluted in FACS buffer according to the manufacturer's protocol. The stained cells were then washed with FACS buffer, washed twice with PBS, overlaid with PBS containing 5 nM DRAQ5 (Biostatus Limited, Leicestershire, UK) and viewed by confocal microscopy.

To detect S1P₁, adherent cells were washed with FACS buffer and fixed/permeabilized in BD Cytofix/Cytoperm solution according to the manufacturer's protocol. Cells were washed and maintained in BD Perm/Wash buffer. Cells were then hybridized with MS1766 or MS2284 and viewed by confocal microscopy according to the same procedure described for detection of S1P₃.

Western Hybridization Analysis of S1P₁ and S1P₃ Receptor Expression. Membrane fractions from stable CHO cells expressing the S1P receptors were separated on 12% Precise Protein Gels (Pierce, Rockford, IL). Precision Plus Protein Standards (Bio-Rad Laboratories) were electrophoresed in adjacent wells for size determinations. Proteins were transferred to a 0.45- μ m Immobilon-P PVDF membrane (Millipore, Billerica, MA) for 2 h at 75 V. The membranes were washed with 1 \times Tris-buffered saline + 0.05% Tween 20 (which was also included in all subsequent wash steps) and blocked with starting block (Tris-buffered saline) blocking buffer (Pierce) containing 0.05% Tween 20. Hybridization of rabbit S1P₁ antiserum (MS1766; 1:1000 dilution) or rabbit S1P₃ antiserum (MS2844; 1:3000) was performed in Starting Block buffer at 4°C for 16 h. After three 5-min washes, the membranes were incubated with a stabilized goat anti-rabbit IgG-HRP conjugated antibody (Pierce) at a 1:3000 dilution (S1P₁) or 1:20,000 dilution (S1P₃) for 1 h at 22°C. Hybridization was detected with the Pierce ECL-femto kit following the manufacturer's protocol, using CL-X Posure film (Pierce).

Results

Homology Modeling of the S1P₁ and S1P₃ Receptors.

To model the structures of the S1P receptors, we aligned their primary amino acid sequences with other members of the GPCR A subfamily to optimize the sequence alignment. Bovine rhodopsin was used as the structural template for the homology model. The alignment of TMs 3 to 7 of S1P receptors with bovine rhodopsin is illustrated in Fig. 2. The most conserved residues in the family A GPCRs are conserved in six of the seven TM domains in S1P receptors, except TM5. The most highly conserved Pro (5.50) in TM5 of the family A GPCRs is replaced by hydrophobic residues in the S1P recep-

tors (i.e., Leu in S1P₁, Ile in S1P₂, S1P₃ and S1P₅, and Val in S1P₄) (Fig. 2). However, another highly conserved residue, Tyr (5.58) (Bosch et al., 2005), is present in all five S1P receptors. In many of the family A GPCRs, a disulfide bond exists between TM3 and the second extracellular loop between TM4 and TM5 (Bosch et al., 2005). For example, in bovine rhodopsin, the disulfide bond is formed between residue Cys110(3.25) and Cys187 (Palczewski et al., 2000). This disulfide bond does not exist in the S1P receptors, which contain a Trp in TM3 in place of Cys at position 3.25.

The S1P₁ and S1P₃ receptors share the highest degree of amino acid sequence relatedness in the S1P receptor family, with approximately 50% of the residues identical, another 20% of the residues strongly similar, and more than 10% of the residues weakly similar. Because the S1P₁ and S1P₃ receptors are highly conserved, the S1P₁ homology model was used for docking of agonists. The S1P₁ homology model displays a three-dimensional structure similar to that of bovine rhodopsin, with a 7TM helical bundle and a short cytoplasmic helix (Fig. 3). The S1P₃ receptor was modeled based on the S1P₁ homology model, focusing on the nonconserved residues.

Structure of the Agonist Binding Pocket of the S1P₁ and S1P₃ Receptors. The compounds used in this study included the natural ligand S1P, FTY720-P (a phosphate ester of FTY720), and compounds A and B, which are S1P₁-selective agonists (Fig. 1). These compounds share common structural characteristics including charged head groups and long lipophilic side chains. The *S*-enantiomeric phosphate ester of FTY720-P was used to generate models of agonist-bound S1P₁ receptor complexes for several reasons. It is a more potent agonist of the human S1P₁ receptor than the *R*-enantiomer (Hale et al., 2004b) and is an agonist of S1P₃, S1P₄, and S1P₅. The *R*-enantiomer is a full agonist of S1P₁ and S1P₄ but its potency at these receptors is lower and it is

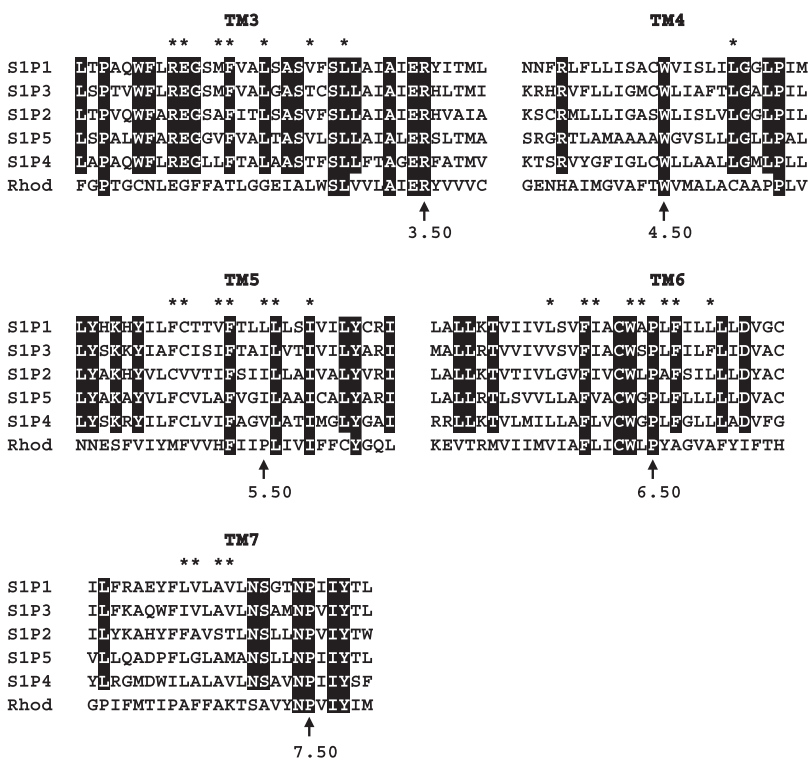

Fig. 2. Alignment of amino acid sequences of TM3, TM4, TM5, TM6, and TM7 in the S1P receptors with bovine rhodopsin. Conserved residues are shown in black boxes. The most conserved residues in each helix are marked by an arrow and labeled with the Ballesteros-Weinstein index. Residues that are also conserved in the TM helices of rhodopsin are also shaded in black. Asterisks above the alignments denote residues predicted to be located within 4 Å of ligand in the docking models of S1P₁ with S1P, FTY720-P, compound A, or compound B.

an antagonist of S1P₃ and S1P₅. At the time these experiments were initiated, the agonist/antagonist activities and affinities of the enantiomeric phosphate esters of S1P against the S1P receptor family were also unknown.

In the agonist docking models, S1P, FTY720-P, and the S1P₁-selective compounds A and B bind to a common pocket that contains conserved receptor-agonist interactions. The preferred docking mode for agonists in these models is depicted in Fig. 3, in which FTY720-P is illustrated. The agonists are bound in the upper half of the TM helical bundle, toward the extracellular surface. The agonists have an extended conformation in a narrow binding pocket and are surrounded by residues mainly from TMs 3, 5, and 6, and a few residues from TMs 4 and 7. Amino acid residues with any atom located within 4 Å of ligands in the docking models are indicated with asterisks in Fig. 2 and are highlighted in green or yellow [Leu276(6.55)] in Fig. 3.

Further examination of receptor residues within 4 Å of the agonists in the binding pocket identified two groups of interactions (Fig. 4). The first group consists of the charged residues on TM3, Arg120(3.28) and Glu121(3.29), identified by Parrill and colleagues (Parrill et al., 2000; Inagaki et al., 2005; Jo et al., 2005). These receptor residues interact with the charged head groups of agonists in our models. For example, the distance between the anionic phosphate group of FTY720-P and the positively charged side chain of Arg120(3.28) of S1P₁ is approximately 2.5 Å; likewise, the ammonium of FTY720-P is within 2.6 Å of the negatively charged side chain of Glu121(3.29) (Fig. 4B). The second group of interactions consists of nine aromatic and hydrophobic amino acids, adjacent to the lipophilic side chains of the agonists. These residues include Phe125(3.33), Leu128(3.36), Phe205(5.42), Phe210(5.47), Phe265(6.44), Trp269(6.48), Leu272(6.51), Phe273(6.52), and Leu276(6.55). Eight of these residues are conserved between S1P₁ and S1P₃ receptors. The ninth residue, Leu276(6.55) in S1P₁, is replaced by Phe263(6.55) in S1P₃ (Fig. 2). In the S1P₁-agonist docking models, Leu276(6.55) forms van der Waals interactions with the phenyl ring and azetidine of compounds A and B (Fig. 4, C and D). In the S1P₃ model, the bulkier Phe263 residue

reduces the size of the binding pocket and sterically hinders binding of compounds A and B to the receptor. These results suggested that the Leu276/Phe263 residues contribute to the S1P₁/S1P₃ selectivity of compounds A and B.

S1P₁ and S1P₃ Receptor Binding Assays. We developed a competitive receptor binding assay using CHO cells transiently transfected with the S1P₁ and S1P₃ receptors to rapidly assay agonist binding to the receptor mutants. In this assay, S1P inhibited the binding of [³³P]S1P to the S1P₁ and S1P₃ receptors with high affinity (Fig. 5, A and B). When assayed in binding assays using transiently transfected receptors, compound A bound S1P₁ with high affinity and exhibited selectivity for S1P₁ over S1P₃ (Fig. 5).

To investigate the role of the S1P₁ Leu276 and S1P₃ Phe263 residues in the selectivity of compound A, we constructed S1P₁ Leu276Phe and S1P₃ Phe263Leu mutant receptors by site-directed mutagenesis and assayed the abilities of the receptors to bind S1P and compound A in transiently transfected cells. The S1P₁ Leu276Phe and S1P₃ Phe263Leu mutants bound S1P with high affinities similar to those of the wild-type receptors (Fig. 5). The S1P₁-selective compound A bound to the S1P₁ Leu276Phe mutant receptor with lower affinity compared with the wild-type S1P₁ receptor. Conversely, the S1P₃ Phe263Leu mutant receptor bound to compound A with higher affinity compared with the wild-type S1P₃ receptor.

Wild-Type and Mutant S1P Receptors Are Expressed on the Cell Surface of Stable Cell Lines. Stable CHO cell lines expressing the wild-type and mutant S1P₁ and S1P₃ receptors were generated to expand the characterization of the mutant S1P₁ Leu276Phe and S1P₃ Phe263Leu receptors. Expression patterns of the wild-type and mutant receptors in the stable cell lines were characterized by Western hybridization and confocal microscopy. Murine S1P₁ is *N*-glycosylated in the ectodomain on an asparagine residue in CHO cell lines overexpressing the receptor, and this residue is conserved in S1P₂, S1P₄, and S1P₅ (Kohno et al., 2002). The amino-terminal ectodomains of murine S1P₁ and S1P₃ are also truncated in overexpressing CHO cells (Kohno and Igarashi, 2003). We have observed similar findings with the

Fig. 3. Docking model of S1P₁ in complex with FTY720-P. A, the TM structures of S1P₁ are shown as gray ribbons with residues within 4 Å of the agonist highlighted in green and Leu276(6.55) highlighted in yellow. FTY720-P is shown in a spheres model, with carbon in purple, oxygen in red, nitrogen in blue, and phosphorus in orange. The hydrogen atoms are omitted for clarity. B, a perpendicular view of the TM helices of S1P₁ in complex with FTY720-P. The loop regions and the cytoplasmic helix were removed for clarity. The TM helices are shown as gray ribbons with residues located within 4 Å of ligand highlighted in green and Leu276(6.55) highlighted in yellow. The side chains of Arg120 (3.28) and Glu121(3.29) are shown in stick form with carbon atoms in green, oxygen atoms in red, and nitrogen atoms in blue. Leu276(6.55) is shown in stick form in yellow. The pictures were prepared by PyMOL (DeLano Scientific LLC, South San Francisco, CA).

stable cell lines expressing the human wild-type and mutant S1P₁ and S1P₃ receptors. The predicted size of the flag-tagged human S1P₁ receptors in these experiments is 44.3 kDa. The S1P₁-specific antiserum recognizes proteins of approximately 54.3, 49.2, and 44.5 kDa in membranes prepared from the cell lines expressing the wild-type receptor and proteins of approximately 54.3 and 49.2 kDa in membranes prepared from the cell line expressing the Leu276Phe S1P₁ receptor (Fig. 6A). Results from these experiments indicate that the stable cell line expressing the S1P₁ Leu276Phe receptor expressed approximately 5-fold more receptor than the cell line expressing the wild-type receptor. The sizes of the human S1P₁ wild-type and Leu276Phe receptors expressed in CHO cells indicate that these receptors are glycosylated. We have also observed that the wild-type and mutant S1P₁ receptors do not cross-react with an antibody that recognizes the Flag tag (data not shown), indicating that human S1P₁ receptors are also truncated at the N terminus. Proteins of approximately 47.7 kDa were detected in membranes from the cell lines expressing the S1P₃ wild-type and Phe263Leu receptors (Fig. 6B). The predicted sizes of the flag-tagged S1P₃ receptors are 43.8 kDa, suggesting that the

receptors are migrating anomalously or are post-translationally modified. The wild-type and mutant S1P₃ receptors were also not recognized by the Flag antibody (data not shown), indicating that the human S1P₃ receptors are also truncated at the N terminus.

We also examined localization of the wild-type and mutant receptors by confocal microscopy (Fig. 7). The S1P₁ antiserum recognized S1P₁ wild-type or Leu276Phe mutant receptors at the cell surface, indicating that the Leu276Phe mutation did not alter trafficking of the receptor in cells. Similar results were obtained when localization of the S1P₃ wild-type and Phe263Leu mutant receptors were examined with the S1P₃ antiserum.

The S1P₁ Leu276Phe and S1P₃ Phe263Leu Mutations Alter the Binding Affinities and Agonist Activities of Compounds A and B. The K_d and B_{max} of the wild-type and mutant receptors in membranes prepared from the stable cell lines were also determined in saturation binding assays with [³³P]S1P (Table 1). The K_d values for the S1P₁ wild-type and Leu276Phe receptors were 0.39 and 0.29 nM, respectively. In these experiments, the B_{max} values of the wild-type and mutant receptors were 9.26 and 13.89 fmoles/ μ g, respec-

Fig. 4. A closer look at agonists in the S1P₁ binding site. Agonists are shown in stick form with carbons in S1P in yellow (A), FTY720-P in purple (B), compound A in cyan (C), and compound B in green (D). Hydrogen atoms are omitted for clarity. Six aromatic residues and Leu276(6.55) in the binding pocket of S1P₁ receptor are shown as gray sticks. For comparison, a Phe residue is depicted in black and overlaid onto the Leu276(6.55) of S1P₁ to model Phe263(6.55) in S1P₃. Oxygen atoms are depicted in red, nitrogen atoms in blue, and phosphorus atoms in orange. The dashed lines illustrate atom pairs within hydrogen bond distance, indicating favorable interactions between the head group of the agonists and the charged residues Arg120(3.28) and Glu121(3.29) on TM3. The pictures were prepared by PyMOL (DeLano Scientific LLC).

tively, indicating that the receptor density of the mutant receptor is higher than that of wild-type S1P₁. These results indicate that the Leu276Phe mutation in S1P₁ does not alter the conformation of the receptor dramatically resulting in a large change in affinity for the ligand. Similar results were observed in saturation binding assays with the S1P₃ wild-type and Phe263Leu mutant receptors. The K_d values for the S1P₃ wild-type and Phe263Leu receptors were 0.23 and 0.22 nM, respectively. The B_{max} values of the stable cell line expressing the wild-type and mutant S1P₃ receptors were 14.24 and 15.98 fmol/ μ g, respectively.

The affinities of S1P, FTY720-P, compound A, and compound B for the wild-type and mutant receptors were assayed in competitive binding assays with membrane fractions prepared from stable clones expressing the wild-type and mutant receptors. Log IC₅₀ values are indicated in Table 2. Unlabeled S1P competed [³³P]S1P from the wild-type and mutant S1P₁ receptors with similar high affinities (Log IC₅₀ values of -9.20 and -9.29 M, respectively). FTY720-P also competed [³³P]S1P from the wild-type and mutant S1P₁ receptors with Log IC₅₀ values of -8.96 and -8.88 M, respectively. The affinities of S1P and FTY720-P for the wild-type and mutant S1P₃ receptors were also comparable. S1P competed [³³P]S1P from the wild-type and mutant S1P₃ receptors with Log IC₅₀ values of -9.35 and -9.29 M, respectively, whereas FTY720-P competed [³³P]S1P from these receptors with Log IC₅₀ values of -8.57 and -8.41 M, respectively.

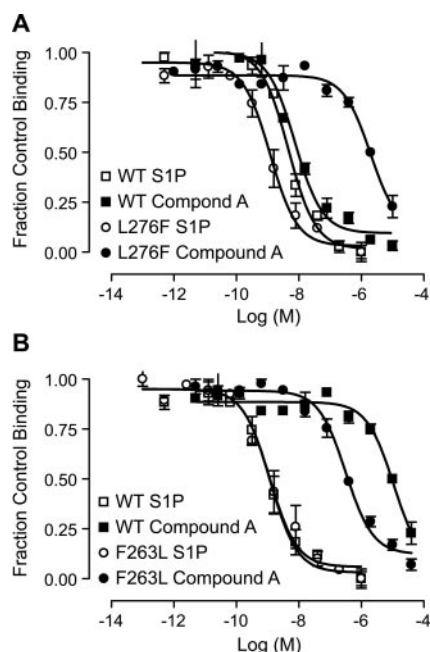

Fig. 5. The S1P₁Leu276Phe and S1P₃ Phe263Leu mutations specifically alter the affinity of the S1P₁ and S1P₃ receptors for compound A. A, data are from a representative competitive binding experiment with CHO cells transiently transfected with the wild-type or mutant S1P₁ receptors. Results (mean \pm range, $n = 2$) are from duplicate determinations in a single experiment and are plotted as the fraction of control binding versus the logarithm of the concentration of the competitor. Similar agonist affinities were seen in several experiments. B, data are from a representative competitive binding experiment with CHO cells transiently transfected with the wild-type or mutant S1P₃ receptors. Results (mean \pm range, $n = 2$) are from duplicate determinations in a single experiment and are plotted as the fraction of control binding versus the logarithm of the concentration of the competitor. Similar agonist affinities were seen in several experiments.

To examine the contribution of S1P₁ Leu276 and S1P₃ Phe263 residues to S1P₁-selective compounds A and B, we determined the Log IC₅₀ values of these compounds for the wild-type and mutant S1P₁ and S1P₃ receptors (Table 2). Compound A bound to the wild-type S1P₁ receptor with approximately 13-fold higher affinity than to the S1P₁ Leu276Phe receptor. The Log IC₅₀ of compound A on the mutant receptor was -7.37 M. The S1P₁-selective agonist compound B bound to wild-type S1P₁ receptor with approximately 40-fold higher affinity than to the Leu276Phe mutant with a Log IC₅₀ of -7.33 M. In contrast, the S1P₁-selective compounds bound with approximately 10- and 151-fold higher affinities to the mutant S1P₃ Phe263Leu receptor compared with the wild-type receptor. The Log IC₅₀ values of compounds A and B for the S1P₃ Phe263Leu mutant were -6.71 and -7.56 M, respectively.

The potencies and efficacies of S1P, FTY720-P, and compounds A and B for the wild-type and mutant receptors were also evaluated in [³⁵S]GTP γ S binding assays (Fig. 8 and Table 3). The basal activities (mean \pm S.E.) of the S1P₁ wild-type and mutant receptors were 1102 \pm 137 and 862 \pm 51 fmol/mg, respectively, and S1P activated the receptors with similar affinities (Log EC₅₀ of -7.48 and -7.58 M, respectively). In our in vitro experiments measuring [³⁵S]GTP γ S binding, the potency of S1P as an agonist of the S1P wild-type and mutant receptors is approximately 50-fold lower than the affinity of S1P for these receptors in competition binding assays. This decrease in potency is due to a phosphatase activity in CHO membrane preparations overexpressing the S1P₁ receptor (J. Milligan, G. J. Shei and S. Mandala, data not shown). This activity hydrolyzes S1P,

Fig. 6. Expression of the S1P₁ Leu276Phe and S1P₃ Phe263Leu receptors. A, Western hybridization analysis of wild-type and mutant S1P₁ and S1P₃ receptors expressed in stable CHO cell lines with S1P₁ antiserum. The following amounts of membrane protein were electrophoresed on the gel: 1 μ g of S1P₁, 0.2 μ g of S1P₁ Leu276Phe, 1 μ g of S1P₃, 1 μ g of S1P₃ Phe263Leu, and 1 μ g of CHO control membrane protein. B, Western hybridization analysis of wild-type and mutant S1P₁ and S1P₃ receptors expressed in stable CHO cell lines with S1P₃ antiserum. The following amounts of membrane protein were electrophoresed: 4 μ g of S1P₁, 1 μ g of S1P₁ Leu276Phe, 1 μ g of S1P₃, 1 μ g of S1P₃ Phe263Leu, and 1 μ g of CHO control membrane protein.

resulting in a loss of potency of the natural agonist in the [³⁵S]GTPγS binding assay. S1P also induced a significant agonist response by the mutant receptor (E_{\max} , 115%). The basal activities (mean ± S.E.) of the S1P₃ wild-type, and mutant receptors were 1555 ± 73 and 2065 ± 50 fmol/mg, respectively. The Log EC₅₀ values of S1P for the wild-type and mutant S1P₃ receptors were -8.45 and -8.64 M, respectively, and S1P activated the S1P₃ mutant receptor efficiently (E_{\max} 82%). The S1P₃ Phe263Leu mutation had minimal effects on the basal activity of the receptor (Fig. 8). Although FTY720-P was a potent and efficacious agonist of the mutant S1P₁ Leu276Phe receptor (Log EC₅₀ = -8.76 M,

E_{\max} = 109%), the compound was a 6-fold more potent agonist of the wild-type receptor (Log EC₅₀ = -9.54 M, E_{\max} = 95%). FTY720-P was also a potent agonist of the wild-type and mutant S1P₃ receptors with Log EC₅₀ values of -8.87 and -9.07 M, respectively. This synthetic agonist also activated the wild-type and mutant S1P₃ receptors effectively with E_{\max} values of 106 and 93%, respectively.

The S1P₁ Leu276Phe and S1P₃ Phe263Leu mutations had significant effects on the agonist potencies of compounds A and B (Fig. 8 and Table 3). The S1P₁-selective compounds A and B were potent and efficacious agonists of the wild-type S1P₁ receptor. The Log EC₅₀ values of the compounds were -8.81 and -9.61 M, respectively. The potencies of S1P₁-selective compounds A and B for the S1P₁ Leu276Phe mutant were lower compared with the wild-type receptor with Log EC₅₀ values of -6.90 and -6.66 M, respectively. Despite a decrease in potency, compounds A and B activated the mutant S1P₁ receptor effectively with E_{\max} values of 103 and 116%, respectively. In contrast, compounds A and B were more potent agonists of the S1P₃ Phe263Leu mutant compared with the wild-type S1P₃ receptor. The Log EC₅₀ values of the compounds against the wild-type S1P₃ receptor were -6.34 and -5.85 M, respectively. Both S1P₁-selective agonists were more potent agonists of the S1P₃ Phe263Leu receptor, with Log EC₅₀ values of -7.97 and -8.98 M, respectively. Both compounds A and B were also effective agonists of the wild-type and mutant S1P₃ receptors with E_{\max} values ranging from 80 to 128%.

Discussion

The S1P receptors share high homology in their primary sequences and, as expected, the agonist binding pockets of the S1P₁ and S1P₃ receptors predicted by our modeling studies overlap and share conserved residues that interact with agonists. This is consistent with findings that many S1P receptor agonists do not exhibit significant receptor subtype selectivity. The potential clinical advantage of S1P receptor agonists lacking S1P₃ activity has prompted development of S1P₁/S1P₃ selective agonists and led us to study receptor-agonist interactions and receptor structural features that contribute to S1P₁/S1P₃ selectivity. Our modeling studies and mutagenesis experiments indicate that Leu276(6.55) in S1P₁ and Phe263(6.55) in S1P₃ are critical residues that contribute to the S1P₁-selectivity of compounds A and B.

In our docking models, the agonists bind S1P₁ in a narrow cavity located in the upper half of the 7TM helical bundle. The binding pocket consists of residues located on TMs 3, 5, 6, and 7. Similar pockets have been identified in many GPCRs by mutagenesis studies and are regarded as a common feature for family A GPCRs (Bondensgaard et al., 2004). Interactions between charged residues on TM3 and charged agonists or antagonists are found in many GPCRs (Feighner et al., 1998; Shin et al., 2002). The importance of S1P interactions with Arg120(3.28) and Glu121(3.29) in the S1P₁ receptor were revealed by mutagenesis studies directed by a model generated from a theoretically calculated structure of bovine rhodopsin (Parrill et al., 2000). Our model, which is based on the X-ray structure of bovine rhodopsin in the dark state, and mutagenesis studies on the human S1P₁ and S1P₃ receptors confirm these findings (data not shown). The

Fig. 7. Localization of the S1P₁ Leu276Phe and S1P₃ Phe263Leu receptors. Stable CHO cell lines expressing the wild-type or mutant S1P₁ and S1P₃ receptors were prepared for immunohistochemistry and confocal microscopy as described under *Materials and Methods*. TABLE 1

Effects of Leu276Phe and Phe263Leu point mutations on the binding of S1P to the S1P₁ and S1P₃ receptors

K_d and B_{\max} were determined in saturation binding assays with [³³P]S1P (3000 Ci/mmol) as described under *Materials and Methods*. Data were analyzed by non-linear regression and fit to a one-site binding model using the program Prism (GraphPad Software). Results are expressed as the mean ± range of two experiments performed in triplicate.

Receptor	K_d nM	B_{\max} fmol/mg
S1P ₁	0.39 ± 0.04	9.26 ± 0.08
S1P ₁ Leu276Phe	0.29 ± 0.01	13.89 ± 0.33
S1P ₃	0.23 ± 0.08	14.24 ± 1.78
S1P ₃ Phe263Leu	0.22 ± 0.04	15.98 ± 1.40

charged residues at the top of the binding pocket interact with the counter-ions in the charged head groups of the agonists. These conserved residues (Fig. 2) play important

roles in recognizing charged agonists in all S1P receptors. Arg120(3.28) is also conserved in LPA receptors, but Glu121(3.29) is substituted with a Gln in LPA receptors.

TABLE 2

The effects of the S1P₁ Leu276Phe, and S1P₃ Phe263Leu mutations on affinities of S1P, FTY720-P, compound A, and compound B

Compound affinities (Log IC₅₀) were calculated from [³³P]S1P binding dose response curves. Results are expressed as the mean ± S.E. of three experiments performed in triplicate.

These LPA receptor residues are key determinants of their ligand specificity (Wang et al., 2001).

The hydrophobic domain of the proposed binding pocket of the S1P₁ receptor is adjacent to the lipophilic side chain of the agonists used in this study. Based on our docking models, a group of aromatic and hydrophobic residues lines the wall of the binding pocket. These residues are located deep in the pocket and provide important interactions with the lipophilic side chain of the agonists. Some of these residues, Phe125(3.33), Phe273(6.52), and Trp269(6.48), have also been proposed to interact with S1P₁ agonist SEW2871 (Jo et al., 2005). S1P₁ residues Phe210(5.47), Phe265(6.44), and Trp269(6.48) are among a group of highly conserved residues in many family A GPCRs (Bondensgaard et al., 2004). Previous mutagenesis studies illustrate the importance of aromatic residues in TM3 and -6 in the binding and activation of GPCRs by agonists (Spalding et al., 1998; Renzetti et al., 1999; Holst et al., 2004).

Our examination of the predicted agonist binding pockets of S1P₁ and S1P₃ identified a nonconserved Leu at position 6.55 in S1P₁. Four of five S1P receptors also contain a Leu at this position, whereas S1P₃ contains a Phe residue at the equivalent position. In our models, Leu276 in S1P₁ and Phe263 in S1P₃ affect the sizes of the binding pockets. The volume of the Phe aromatic side chain is approximately 25% larger than that of the aliphatic Leu side chain, making the S1P₃ binding pocket more crowded than the S1P₁ pocket. In the S1P₁ docking models, Leu276(6.55) is close to the phenyl ring and azetidine of S1P₁-selective compounds A and B (Fig. 4, C and D). The rigidity of these regions of compounds A and B makes it difficult for them to assume conformations that fit in the smaller binding pocket of the S1P₃ receptor, explaining their S1P₁ selectivity. When Leu276(6.55) is replaced with a Phe in the S1P₁ model, the binding pocket is smaller because of the bulkier size of the Phe side chain.

To test this model, we constructed S1P₁ and S1P₃ receptor mutants in which the Leu276 and Phe263 residues were exchanged and examined their expression and activity in Western hybridization, confocal microscopy, and radioligand binding experiments. These experiments indicate that the S1P₃ wild-type and mutant receptors are overexpressed on the surface of the stable CHO cell lines at similar densities and that both receptors bind S1P with high affinity. The K_d values of S1P for both receptors are approximately 0.2 nM. S1P binds the wild-type and mutant S1P₁ receptors with high affinity, with K_d values of 0.39 and 0.29 nM, respectively. The S1P₁ receptors are overexpressed on the surface of the stable CHO cells. Results from the Western hybridization experiments indicate that the mutant receptor is expressed at approximately 5-fold higher density than the wild-type receptor, whereas our ligand binding studies with [³³P]S1P indicate that the mutant receptor density is approximately 2-fold higher than the wild-type receptor. These results indicate that a fraction of the S1P₁ Leu276Phe receptors may be in a conformation that does not bind S1P with high affinity.

The competitive ligand binding and agonist functional studies comparing the S1P₁ and S1P₃ wild-type and mutant receptors confirm the predictions of the molecular models we developed for these receptors. The S1P₁ Leu276Phe mutant has a significantly reduced affinity for S1P₁-selective compounds A and B, and both of these agonists activate the S1P₁ mutant with much poorer potencies. On the other hand, substituting Phe263(6.55) of the S1P₃ receptor with Leu in the S1P₃ receptor

enlarges the binding pocket of this mutant S1P₃ receptor, leading to an increase in the binding affinity and agonist potency of compounds A and B. This prediction was also verified experimentally with the S1P₃ Phe263Leu mutant. In addition, our conformational analyses of compounds A and B indicate that compound B is more rigid than compound A (data not shown), making it more difficult to assume a conformation that fits the binding pocket of the S1P₃ receptor and more susceptible to changes at Leu276 and Phe263 of the S1P₁ and S1P₃ receptors, respectively. Our in vitro analyses of the interactions of compounds A and B with the wild-type and mutant receptors demonstrate that the mutations have more dramatic effects on the binding affinity and agonist potency of compound B.

In contrast to S1P₁-selective compounds A and B, S1P contains a long, highly flexible alkyl side chain that easily adopts a conformation to bind to S1P₁ and S1P₃. It binds to both receptors with comparable affinities and is not sensitive to the Leu and Phe substitution mutations we constructed in S1P₁ and S1P₃. FTY720-P is also a high-affinity agonist of S1P₁ and S1P₃ with a slightly higher agonist potency against S1P₁. Our models predict that FTY720-P has a higher potency for S1P₁ because it contains a phenyl ring and prefers a larger binding pocket. The phenyl ring of FTY720-P is four bonds away from the positively charged ammonium group and seven bonds away from the negatively charged phosphate group. The longer linker between the charged head group and the phenyl ring of FTY720-P is more flexible than the azetidine moiety in S1P₁-selective compounds A and B. The models suggest that this flexibility is the reason FTY720-P is affected less by changes of the Leu276 and Phe263 residues in the binding pockets of S1P₁ and S1P₃. Although significant changes in FTY720-P binding affinity for the mutant or wild-type receptors were not observed in competition binding assays, the S1P₁ Leu276Phe mutation did confer a statistically significant change in agonist potency measured in vitro. FTY720-P activates the wild-type S1P₁ receptor 6-fold more potently than the S1P₁ Leu276Phe receptor, which contains a significantly smaller binding pocket.

These models predict that residues Leu276(6.55) and Phe263(6.55) are important contributors to S1P₁ and S1P₃ specificities of compounds A and B. However, the changes in agonist binding affinities and potencies observed with these mutations do not fully interconvert the pharmacological profiles of either agonist, indicating that other residues within the binding pocket also contribute to the specificities of these subtype-selective agonists. There are seven nonconserved residues in S1P₁ and S1P₃ within 4 Å of the predicted agonist binding pocket (Val3.40Thr, Val5.46Ile, Leu5.50Ile, Leu6.41Val, Ala6.49Ser, Leu6.55Phe, and Leu7.39Ile). Except for Leu276Phe, these residues are predicted to have smaller effects on the specificities of compounds A and B based on their positions and orientations. Combining the S1P₁ Leu276Phe or S1P₃ Phe263Leu mutations with amino acid substitutions in the other six nonconserved residues in S1P₁ and S1P₃ in the predicted agonist binding pocket may interconvert the pharmacological profiles of these agonists completely. Models of GPCR-agonist complexes based on X-ray crystal structures of rhodopsin in the unactivated "dark state" also have an inherent bias that might mask important receptor interactions with agonists.²

Our integrated molecular modeling and site-directed mutagenesis studies of the S1P₁ and S1P₃ receptors bound to

nonselective and S1P₁-selective agonists provide additional insights into the nature of different S1P receptor-agonist interactions and identify an important pair of residues in S1P₁ and S1P₃ that contribute significantly to receptor subtype selectivity of compounds A and B and FTY720-P. These findings provide a molecular basis for understanding S1P₁/S1P₃ subtype-selectivity of these S1P receptor agonists, which should aid development of more selective S1P₁ receptor agonists with immunosuppressive properties and improved safety profiles.

Acknowledgments

We are grateful to Hugh Rosen for encouragement and support in the early stages of this work. We thank James Milligan for synthesis of the radioligand used in the saturation binding assays, members of the Mandala laboratory for assay protocols and help in screening and characterizing antiserum MS2284, and Kevin Lynch for providing the expression plasmids encoding the human S1P₁ and S1P₃ receptors. We are also grateful to Michele McColgan and Sharon O'Brien for preparing the figures and Elizabeth Quackenbush for comments on the manuscript.
