(Dated: May 27, 2011)

We show that under a certain condition of local commutativity the minimum von-Neumann entropy output of a quantum channel is locally additive. We also show that local minima of the 2-norm entropy functions are closed under tensor products if one of the subspaces has dimension 2.

Let $K$ be a subspace of the $m \times n$ complex matrices, and let $x \in K$, $\text{Tr}[xx^*] = 1$. Then the von Neumann entropy of $x$ is

$$H(x) := -\text{Tr}[xx^* \ln xx^*],$$

and the minimum entropy output of the subspace $K$ is

$$H(K) := \min_{x \in K, \text{Tr}[xx^*]=1} H(xx^*).$$

Recently, Hastings [1] disproved the famous additivity conjecture, which posited that

$$H(K_1 \otimes K_2) = H(K_1) + H(K_2). \quad (1)$$

This conjecture was considered one of the most significant open problems in quantum information theory, spawning a large literature [2]. Its importance was motivated in part by the problem of finding the classical capacity of a quantum channel, and in part by a result of Peter Shor [3] that showed that a number of apparently distinct additivity conjectures, including the additivity of the minimum entropy output of a quantum channel, the additivity of the entanglement of formation, and the additivity of the Holevo capacity, were all equivalent.

Hastings’ counterexample showed that the von Neumann entropy function is not globally additive on subspaces: in other words, if $x_1$ is a global minimum in $K_1$ and $x_2$ is a global minimum in $K_2$, then $x_1 \otimes x_2$ is not necessarily a global minimum in $K_1 \otimes K_2$. On the other hand, in this paper we show that under certain conditions the von Neumann entropy output is locally additive. More precisely, we show that if $K_i$ is a subspace with a local minimum $x_i$, and $x_i x_i^*$ commutes with $x_i y_i^*$ for every $y_i \in K_i$, then $x_1 \otimes x_2$ is a local minimum of $K_1 \otimes K_2$; we call this condition the local commutativity condition. More generally, we study the behavior of entropy functions of the eigenvalues of $xx^*$, and we consider when the tensor product of two local minima is again a local minimum.

The paper is organized as follows. In Section II we analyze the local commutativity condition. In Section III we consider the first derivative of the entropy function and note that critical points of the von Neumann and Renyi entropies are closed under tensor products. These results are due to a group participating in the American Institute for Mathematics workshop on “Geometry and representation theory” [4]. In Section IV we consider the second derivative of the von Neumann entropy function, and show that local minima of von Neumann entropy are closed under tensor products, given the previously mentioned commutativity assumption. Finally, in Section V we consider the second derivative of the 2-norm entropy function. We show that local minima of the 2-norm are closed under tensor products if one of the subspaces has dimension 2. In the Appendix A we analyze the affine parametrization and use it to derive a necessary condition for local minima. In Appendix B we show that there is a simple counterexample for the additivity conjecture over the real numbers.

I. THE LOCAL COMMUTATIVITY CONDITION

For a given function $f : [0, \infty) \to (-\infty, \infty)$ we define $f(x) = \sum_{i=1}^n f(\lambda_i(xx^*))$ for $x \in \mathbb{C}^{m \times n}$, and $\lambda_i$ are the eigenvalues of $xx^*$. We assume that either $f$ is smooth on $[0, \infty)$, i.e., has two continuous derivatives at every $t \geq 0$, or $f(t) = H(t) \equiv -t \log t$. Let $D_y f(x), D_y^2 f(y)$ denote the first and the second derivative of $f$ in the $y$ direction:

$$D_y f(x) = \frac{d}{de} f(x + ey)|_{e=0}, \quad D_y^2 f(x) = \frac{d^2}{de^2} f(x + ey)|_{e=0}$$

Then $x$ is a critical point if and only if $D_y f(x) = 0$ for each $y \in K$ (in the next section we will discuss in more details this condition).

Here we focus on the function $f(t) = H(t) \equiv -t \log t$. In this case we need to be very careful when dealing with $xx^*$ which have zero eigenvalues. We will see that for any...
Lemma 1. Let \( x, y \in \mathbb{C}^{m \times n} \), \( \text{Tr}(xx^*) > 0 \) and \( H(t) = -t \log t \). Then \( D_y H(x) \in \mathbb{R} \). Change standard orthonormal bases in \( \mathbb{C}^m, \mathbb{C}^n \) to new orthonormal bases such that \( x, y \) have the forms

\[
x = \begin{bmatrix} x_{11} & 0_{r,n-r} \\ 0_{m-r,r} & 0_{m-r,n-r} \end{bmatrix} \quad \text{and} \quad y = \begin{bmatrix} y_{11} \ y_{12} \\ y_{21} \ y_{22} \end{bmatrix},
\]

with \( 0_{i,j} \in \mathbb{C}^{i \times j} \) and \( x_{11}, y_{11} \in \mathbb{C}^{r \times r} \). Then \( D^2_y f(x) = \infty \) if and only if \( y_{22} \neq 0 \).

Proof. By considering \( UKV \), where \( U, V \) unitary we may assume that \( x, y \) in the form (2). Furthermore \( x_{11} = D \equiv \text{diag}(d_1, \ldots, d_r) \), where \( d_1 \geq d_2 \geq \ldots \geq d_r > 0 \) and \( r \) is the rank of \( x \). So \( d_i \) is the \( i \)-th singular value, \( \sigma_i(x_{11}) \) for \( i = 1, \ldots, r \). Observe next that

\[
\text{Tr}((x + ey)(x + ey)^*) = \sum_{i=1}^m \lambda_i((x + ey)(x + ey)^*).
\]

We assume here that the eigenvalues of a hermitian matrix are arranged in a nonincreasing order. Note that

\[
(x + ey)(x + ey)^* = xx^* + \epsilon(xy^* + yx^*) + \epsilon^2(yy^*)
\]

Hence

\[
\lambda_i((x + ey)(x + ey)^*) = \lambda_i(xx^* + \epsilon(xy^* + yx^*) + O(\epsilon^2)).
\]

Observe next that

\[
xx^* + \epsilon(xy^* + yx^*) = \begin{bmatrix} D + \epsilon(Dy_{11} + y_{11}D) & \epsilon Dy_{21} \\ \epsilon y_{21} D & 0 \end{bmatrix}
\]

For small \( \epsilon \), the first variation formula (see [3]) yields

\[
\lambda_i((x + ey)(x + ey)^*) = d_i + \epsilon \lambda_i + O(\epsilon^2) \quad \text{for} \quad i = 1, \ldots, r,
\]

\[
\lambda_i((x + ey)(x + ey)^*) = O(\epsilon^2) \quad \text{for} \quad i > r.
\]

Hence \( \lambda_i((x + ey)(x + ey)^*) = d_i^r \epsilon^2 + O(\epsilon^3) \) for \( i > r \), with \( d_{r+1}^r \geq \ldots \geq d_m^r \geq 0 \). These calculations show that

\[
H(x + ey) = H(D + ey_{11}) - \sum_{i=r+1}^m d_i^r \epsilon^2 \log(d_i^r \epsilon^2) + O(\epsilon^2).
\]

Hence \( D_y H(x) \in \mathbb{R} \) and \( D^2_y H(x) = \infty \) if and only if \( d_{r+1}^r > 0 \). It is left to show that \( d_{r+1}^r \) is 0 if and only if \( y_{22} \neq 0 \). Consider \( \Lambda^{r+1}(x + ey) \), the \( r + 1 \) compound matrix of \( x + ey \). (Recall that \( \Lambda^{r+1}(x + ey) \) is the \( (r+1) \times (r+1) \) matrix whose entries are \((r+1) \times (r+1)\) minors of \( x + ey \).) Note that \( \Lambda^{r+1}(x + ey) \) is a polynomial matrix in \( \epsilon \). Since \( x \) has rank \( r \) it follows that \( \Lambda^{r+1}(x + ey) = 0 \). Hence \( \Lambda^{r+1}(x + ey) = c_1 + c_2 \epsilon(\epsilon) \), where \( c_1 \) is a constant matrix and \( c_2 \) is a polynomial matrix in \( \epsilon \). We claim that \( z_1 = 0 \) if and only if \( y_{22} = 0 \). Indeed since \( D \) is diagonal then a minor of order \( r + 1 \) that can have a nonzero derivative at \( \epsilon = 0 \) is the minor based on the rows \( \alpha = \{1, \ldots, r\} \) and columns \( \beta = \{1, \ldots, r\} \).

Denote this minor by \( \det(x + ey)_{\alpha, \beta} \). Clearly \( \det(x + ey)_{\alpha, \beta} = \det(\epsilon(c_1 + c_2 \epsilon(\epsilon))) = \det(\epsilon(\epsilon))_{\alpha, \beta} + O(\epsilon^2) \), where \( p, q \) entry of \( y \). So if \( y_{22} = 0 \) we obtain that \( z_1 = 0 \). Hence

\[
\|\Lambda^{r+1}(x + ey)\|_2 = \sigma_1(\Lambda^{r+1}(x + ey)) \leq \epsilon^2 a \quad \text{for some positive} \ a. \quad \text{Recall that}
\]

\[
(\sigma_1(\Lambda^{r+1}(\xi + ey)))^2 = \prod_{i=1}^{r+1} \lambda_i((x + ey)(x + ey)^*).
\]

As \( \sigma_1(\Lambda^{r+1}(\xi + ey)))^2 \leq \epsilon^2 a^2 \), we deduce that \( d_{r+1}^r = 0 \).

It is left to show that if \( y_{p,q} \neq 0 \) for some \( p, q > r \), then \( d_{r+1}^r > 0 \). Clearly,

\[
\|\Lambda^{r+1}(x + ey)\|_2 \geq |\det(x + ey)_{\alpha, \beta}| = d_1 \ldots d_r \epsilon |y_{p,q}| \epsilon^r \quad \text{for some small value of} \ \epsilon. \quad \text{(The first inequality follows from the fact the} \ \ell_2 \text{norm of a matrix is not less than the absolute value of any of its entries.)} \quad \text{This shows that} \quad d_{r+1}^r > 0.
\]

The lemma above implies that for the purpose of calculating local minima, without loss of generality, we can always take the directional derivatives in a direction with \( y_{22} = 0 \). In the lemma above, however, we did not impose the normalization condition \( \text{Tr}(xx^*) = 1 \). As we show in the next lemma, it does not affect the result that \( D^y H = \infty \) if and only if \( y_{22} = 0 \).

Lemma 2. Let \( x, y \in \mathbb{C}^{m \times n} \), with \( \text{Tr}(xx^*) = 1 \) and \( y \neq 0 \). Consider the matrix

\[
x(y, \epsilon) := \frac{1}{\sqrt{\text{Tr}(xx^*)}}(x + ey),
\]

which is always defined for small \( \epsilon \). Then \( \frac{d}{d\epsilon} H(x(y, \epsilon))|_{\epsilon=0} \in \mathbb{R} \), and \( \frac{d^2}{d\epsilon^2} H(x(y, \epsilon))|_{\epsilon=0} = \infty \) if and only if \( D^2_y f(0) = \infty \).

Proof. The functions \( h_1(\epsilon) := (\text{Tr}(x + ey)(x + ey)^*)^{-1} \) and \( h_2(\epsilon) := \log(\text{Tr}(x + ey)(x + ey)^*) \) are analytic in the neighborhood of \( \epsilon = 0 \), and clearly

\[
H(x(y, \epsilon)) = h_1(\epsilon) f(\epsilon) + h_2(\epsilon).
\]

As \( h_1(0) = 1 \) we obtain

\[
\frac{d}{d\epsilon} H(x(y, \epsilon))|_{\epsilon=0} = D_y f(0) + h_1'(0) H(x) + h_2'(0) \in \mathbb{R},
\]

while \( \frac{d^2}{d\epsilon^2} H(x(y, \epsilon))|_{\epsilon=0} \) consists of \( D^2_y f(0) \) plus finite terms. The lemma follows.
The two lemmas above imply the following characterization of the local commutative condition discussed in the introduction.

**Lemma 3.** Let the assumptions of Lemma 1 hold. Assume that $x, y$ are in the form $x = x^\perp + y^\perp$ and only if $y_1 = 0$ and $x_1 x_1^\perp$ commutes with $x_1 y_1^\perp$. (This is equivalent to $x_1^2 x_1^\perp y_1^\perp = y_1 x_1 x_1^\perp$.)

**Proof.** Write $x$ and $y$ as in (2). The assumption that $x_1$ is invertible, and $x^\perp$ commutes with $x^\perp$ is equivalent to $y_2 = 0$ and $x_1 x_1^\perp$ commutes with $x_1 y_1^\perp$. So $x_1 x_1^\perp x_1 x_1^\perp = x_1 y_1^\perp x_1 x_1^\perp$. Divide both sides of this equalities by $x_1$ to obtain the lemma.

In particular, the above lemma together with the theorem in Section II imply that local additivity holds for subspaces consisting of matrices $y$ as in Eq. (2), with $y_{11}$ diagonal, $y_{21} = 0$, and $y_{12}$ arbitrary.

**II. FIRST DERIVATIVE OF ENTROPY FUNCTIONS UNDER TENSOR PRODUCTS**

All of the results in this section are due to the “Quantum Information Group” participating in the workshop “Geometry and representation theory”, held at the American Institute for Mathematics [3]; we record the results here for completeness.

For a given function $f(t)$ as defined above, let $D_y f(x)$ denote the derivative of $f$ in the $y$ direction:

\[ D_y f(x) = \frac{d}{dt} f(x + ty)|_{t=0}. \]

Then $x$ is a critical point if and only if $D_y f(x) = 0$ for every $y$. Since we are interested in local minima in $K$ subject to $\text{Tr}[xx^\perp] = 1$, we restrict $y$ to the tangent space $\{y \in K : D_y \text{Tr}[xx^\perp] = 0\} \cap \{y \in K : \text{Tr}[xy^\perp + yx^\perp] = 0\}$. Also, we restrict our attention to functions $f(x)$ which depend only on $xx^\perp$. Since $xx^\perp$ is invariant under $x \rightarrow ix$, we may ignore $y = ix$. That is, $x \in K$ is critical if and only if $D_y f(x) = 0$ for every $y$ in the orthogonal subspace $x^\perp := \{y \in K : \text{Tr}[yx^\perp] = 0\}$.

Under tensor products, the orthogonal subspace has the following decomposition:

\[ (x_1 \otimes x_2)^\perp = \langle x_1 \rangle \otimes x_2^\perp \oplus x_1^\perp \otimes \langle x_2 \rangle \oplus x_1^\perp \otimes x_2^\perp. \]

For a function $f(x)$ depending only on $xx^\perp$, a point $x \in K$ is critical in $K$ if and only if $D_y f(x) = 0$ for every $y \in x^\perp$. In general, given a univariate differentiable function $F$, a Taylor series expansion of $F$ shows that the matrix function $a \mapsto \text{Tr}[F(a)]$ has directional derivative

\[ \frac{d}{dt} \text{Tr}[F(a + eb)]|_{t=0} = \text{Tr}[F'(a)b]. \]

We are interested in the case $a = xx^\perp$ and $b = xy^\perp + yx^\perp$: if $f(x) = \text{Tr}[F(xx^\perp)]$, then

\[ D_y f(x) = \text{Tr}[F'(xx^\perp)(xy^\perp + yx^\perp)]. \]

This derivative is zero for all $y \in x^\perp$ if and only if $\text{Tr}[F'(xx^\perp)xy^\perp] = 0$ for all $y \in x^\perp$.

**Theorem 1.** Let $F$ be a differentiable univariate function such that $F'(a_1 \otimes a_2)$ is in the span of

\[ \{F'(a_1) \otimes F'(a_2), F'(a_1) \otimes I, I \otimes F'(a_2), I = I \}. \]

If $x_1$ and $x_2$ are critical points of $f(x) = \text{Tr}[F(xx^\perp)]$ subject to $\text{Tr}[xx^\perp] = 1$, then so is $x_1 \otimes x_2$.

**Proof.** Let $x = x_1 \otimes x_2$. It suffices to show that $D_y f(x) = 0$ for all $y_1 \in x_1^\perp$, then $D_y f(x) = 0$ for all $y \in x^\perp$. That is, if $\text{Tr}[F'(x_1 x_1^\perp)xy^\perp] = 0$, then $\text{Tr}[F'(xx^\perp)xy^\perp] = 0$.

First, suppose $y = y_1 \otimes y_2$, for some arbitrary $y_1$ and $y_2$, and consider the term in $F(xx^\perp)$ proportional to $F'(x_1 x_1^\perp) \otimes F'(x_2 x_2^\perp)$: we have

\[ \text{Tr}[(F'(x_1 x_1^\perp) \otimes F'(x_2 x_2^\perp)(xy^\perp))] = \text{Tr}[F'(x_1 x_1^\perp)xy_1^\perp] \text{Tr}[F'(x_2 x_2^\perp)yx_2^\perp], \]

which is 0 provided that either $y_1 \in x_1^\perp$ or $y_2 \in x_2^\perp$ (or both). Likewise, for the term proportional to $F'(x_1 x_1^\perp) \otimes I$,

\[ \text{Tr}[(F'(x_1 x_1^\perp) \otimes I)(xy^\perp)] = \text{Tr}[F'(x_1 x_1^\perp)yx_1^\perp] \text{Tr}[F'(x_2 x_2^\perp)yx_2^\perp], \]

which again is 0 if either $y_1 \in x_1^\perp$ or $y_2 \in x_2^\perp$. Similarly, $\text{Tr}[(I \otimes F'(x_2 x_2^\perp))(xy^\perp)] = 0$ and $\text{Tr}[(I \otimes I)(xy^\perp)] = 0$. Combining the terms which make up $F'(xx^\perp)$, we see that $\text{Tr}[(F'(xx^\perp)xy^\perp)] = 0$ whenever $y = y_1 \otimes y_2$ satisfies $y_1 \in x_1^\perp$ or $y_2 \in x_2^\perp$.

Now an arbitrary element $y \in x^\perp$ can be written as a linear combination of terms of the form $x_1 \otimes y_1$, $y_1 \otimes x_2$, and $y_1 \otimes y_2$, with $y_1 \in x_1^\perp$. For each of these terms either the first or second component of the tensor product is in $x_1^\perp$. Therefore $\text{Tr}[F'(xx^\perp)xy^\perp] = 0$ for all $y \in x^\perp$.

Our main interest is in the function $x \mapsto -\text{Tr}[xx^\perp \ln xx^\perp]$, which is proportional to the usual von Neumann entropy of the matrix $xx^\perp$. Letting $F(t) = -t \ln t$, so that $F'(t) = -(1 + \ln t)$, we have

\[ F'(a_1 \otimes a_2) = -I - \ln(a_1 \otimes a_2) = -I \otimes I - \ln(a_1) \otimes I - I \otimes \ln(a_2) \in \text{span} \{I \otimes I, F'(a_1) \otimes I, I \otimes F'(a_2)\}. \]

(Here we used the fact that $\ln(a_1 \otimes a_2) = \ln(a_1) \otimes I + I \otimes \ln(a_2)$.) Thus the hypotheses of Theorem 1 are satisfied, and so critical points of $x \mapsto -\text{Tr}[xx^\perp \ln xx^\perp]$ are closed under tensor products.

Another important class of entropy functions are the $p$-norms:

\[ x \mapsto \|xx^\perp\|^p_p = \text{Tr}[(xx^\perp)^p]. \]

Letting $F(t) = t^p$, so $F'(t) = pt^{p-1}$, we have

\[ F'(a_1 \otimes a_2) = p(a_1 \otimes a_2)^{p-1} = \frac{1}{p} F'(a_1) \otimes F'(a_2). \]
Again $F(t)$ is in the form of Theorem 1. Thus for both the von Neumann entropy and the $p$-norms, the tensor product of critical points (subject to $\text{Tr}[xx^*] = 1$) are again critical points.

### III. Second Derivative of the Von-Neumann Entropy

In this section we show that under the local commutativity condition, if $x_1 \in K_1$ and $x_2 \in K_2$ are nonsingular strong local minima of

$$x \mapsto -\text{Tr}[xx^* \log xx^*]$$

subject to $\text{Tr}[xx^*] = 1$, then $x_1 \otimes x_2$ is also a strong local minimum in $K_1 \otimes K_2$. More precisely, we assume that if $y_i \in K_i$ is orthogonal to $x_i$, then $x_i x_i^*$ and $x_i y_i^*$ commute. Throughout this section we will also assume without loss of generality that $\text{Tr}[yy^*] = 1$.

In this section we work with the normalized entropy function

$$H(x) := -\text{Tr} \left[ \frac{xx^*}{\|x\|^2} \log xx^* \right].$$

A point $x$ is a strong local minimum of $H$ on $\{x : \text{Tr}[xx^*] = 1\}$ if and only if for every $y$ orthogonal to $x$, the second directional derivative $D_y^2H(x)$ is positive.

**Lemma 4.** Assume $xx^*$ and $xy^*$ commute. Then

$$D_y^2H(x) = 2\text{Tr}[xx^* \log xx^*] - 2\text{Tr}[yy^* \log xx^*]$$

$$-\text{Tr}[(xy^* + yx^*)^2(xx^*)^{-1}],$$

where the last trace is taken over the support of $xx^*$.

**Proof.** For convenience define $a = xx^*$, $b = xy^* + yx^*$, and $c = yy^*$, so that

$$(x + ey)(x + ey)^* = a + eb + e^2c.$$ 

Note that $\text{Tr}[a] = \text{Tr}[c] = 1$ and $\text{Tr}[b] = 0$, so $\text{Tr}[(x + ey)(x + ey)^*] = 1 + e^2$. Then

$$H(x + ey) = -\text{Tr} \left[ \frac{a + eb + e^2c}{1 + e^2} \log \frac{a + eb + e^2c}{1 + e^2} \right]$$

$$= -\text{Tr}[(a + eb + e^2c) \log(a + eb + e^2c) + \log(1 + e^2)].$$

Up to a second order in $e$ this expression becomes

$$H(x + ey) = -\text{Tr} \left[ a \log (a + eb + e^2c) \right]$$

$$- e\text{Tr} \left[ b \log (a + eb) \right] + e^2 (1 + \text{Tr} [a \log a] - \text{Tr} [c \log a]).$$

Therefore, the second order directional derivative can be expressed in the following way:

$$D_y^2H(x) = -\frac{d^2}{de^2} \text{Tr} \left[ a \log (a + eb + e^2c) \right] \Big|_{e=0} -$$

$$2 \left. \frac{d}{de} \text{Tr} \left[ b \log (a + eb) \right] \right|_{e=0} + 2(1 + \text{Tr} [a \log a] - \text{Tr} [c \log a]).$$

To calculate the derivative expressions above, we will express the log function by its Taylor series:

$$\log(a + \varepsilon b) = \log[I - (I - a + \varepsilon b)] = -\sum_{n=1}^{\infty} \frac{(I - a + \varepsilon b)^n}{n}.$$

Without loss of generality (see Lemma 1), in the last equality we assumed that $a$ is invertible, so that for sufficiently small $\varepsilon$ also $a + \varepsilon b$ is invertible and therefore $I - a + \varepsilon b < I$. To calculate the derivative of $\text{Tr}[b \log(a + \varepsilon b)]$ at $\varepsilon = 0$, we only need to take terms proportional to $\varepsilon$ in the expansion of the logarithm. Assuming $a$ and $b$ commute,

$$\left. \frac{d}{d\varepsilon} \text{Tr}[b \log (a + \varepsilon b)] \right|_{\varepsilon=0} = \sum_{n=1}^{\infty} \text{Tr} \left[ b^2 (I - a)^{(n-1)} \right]$$

$$= \text{Tr}[b^2 a^{-1}].$$

To calculate the second derivative of $\text{Tr}[a \log(a + \varepsilon b + \varepsilon^2 c)]$ we need only take the terms proportional to $\varepsilon^2$. Again assuming $a$ and $b$ commute and $a$ is invertible,

$$\left. \frac{d^2}{d\varepsilon^2} \text{Tr}[a \log (a + \varepsilon b + \varepsilon^2 c)] \right|_{\varepsilon=0}$$

$$= -\sum_{n=2}^{\infty} \frac{2}{n} \left( \begin{array}{c} n \\ 2 \end{array} \right) \text{Tr}[a(I - a)^{(n-2)b^2}] + 2 \sum_{n=1}^{\infty} \text{Tr}[a(I - a)^{(n-1)c}]$$

$$= -\text{Tr}[a^{-1}b^2] + 2 \text{Tr}[c] = -\text{Tr}[a^{-1}b^2] + 2.$$

Therefore $D_y^2H(x) = 2\text{Tr}[a \log a] - 2\text{Tr}[c \log a] - \text{Tr}[b^2 a^{-1}]$. 

**Corollary 1.** Assume $xx^*$ and $xy^*$ commute. Then $D_y^2H(x) > 0$ if and only if

$$[\text{Tr}[(xx^*)^{-1}(xy^*)^2]] + [\text{Tr}[(xx^*)^{-1}xy^*yx^*]]$$

$$< \text{Tr}[xx^* \log xx^*] - \text{Tr}[yy^* \log xx^*],$$

where $(xx^*)^{-1}$ is the inverse over the support of $xx^*$.

**Proof.** Expand $(xy^* + yx^*)^2$ into four terms, noting that $xy^*$ and $yx^*$ commute with $(xx^*)^{-1}$. Then $D_yH(x) > 0$ if and only if

$$\text{Tr}[(xx^*)^{-1}(xx^*)^2] + \text{Tr}[(xx^*)^{-1}yy^*yx^*] + 2 \text{Tr}[(xx^*)^{-1}xy^*yx^*]$$

$$< -2 \text{Tr}[yy^* \log xx^*] + 2 \text{Tr}[xx^* \log xx^*].$$

The first two terms on the LHS are twice the real part of $\text{Tr}[(xx^*)^{-1}(xy^*)^2]$; the largest value of these two terms over all phases of $y$ is $2 |\text{Tr}[(xx^*)^{-1}(xy^*)^2]|$.

For convenience, denote the terms in Corollary 1 as follows:

$$a(x, y) := [\text{Tr}[(xx^*)^{-1}(xy^*)^2]],$$

$$b(x, y) := [\text{Tr}[(xx^*)^{-1}xy^*yx^*]],$$

$$c(x) := [\text{Tr}xx^* \log xx^*],$$

$$d(x, y) := \text{Tr}[yy^* \log xx^*],$$

(5)
so $D^2_yH(x) > 0$ if and only if $a + b < c - d$. Each of these terms behaves nicely under tensor products:

\[
\begin{align*}
    a(x_1 \otimes x_2, y_1 \otimes y_2) &= a(x_1, y_1) a(x_2, y_2), \\
    b(x_1 \otimes x_2, y_1 \otimes y_2) &= b(x_1, y_1) b(x_2, y_2), \\
    c(x_1 \otimes x_2) &= c(x_1) + c(x_2), \\
    d(x_1 \otimes x_2, y_1) &= d(x_1, y_1) + d(x_2, y_2).
\end{align*}
\]

We can also bound the size of some of these terms for any $x$ and $y$ such that $\text{Tr}[xy^*] = 0$ and $\text{Tr}[xx^*] = \text{Tr}[yy^*] = 1$. First, we claim $b \in [0, 1]$. To see this, note that $P = x^*(xx^*)^{-1}x$ is a projection matrix, so

\[b = \text{Tr}[y^*yx^*(xx^*)^{-1}x] = \|Py^*\|^2,
\]

and $0 \leq \|Py^*\|^2 \leq \|y^*\|^2 = 1$. Second, we claim $a \in [0, b]$. To see this, note that without loss of generality (see Lemma 1) we can assume that $xx^*$ is invertible and therefore positive definite, so $(xx^*)^{-1/2}$ exists and commutes with $y^*$, and so $(xx^*)^{-1}(xy^*)^2 = ((xx^*)^{-1/2}y^*)^2$. By Cauchy-Schwarz,

\[
a = \left| \text{Tr}[(xx^*)^{-1/2}y^*x] \right| \\
\leq \text{Tr}[((xx^*)^{-1/2}y^*)(xx^*)^{-1/2}y^*]^* = b.
\]

Thirdly, we claim that $c \leq 0$, since it is the negative of the entropy function. We are now ready to prove the main result of this paper.

**Theorem 2.** Suppose $x_1$ and $x_2$ are strong local minima of $x \mapsto -\text{Tr}[xx^* \log xx^*]$ subject to $\text{Tr}[xx^*] = 1$ and $x_i \in K_i$, where $K_i$ is a subspace. Further assume that for every $y_i \in K_i$, the matrices $x_i x_i^*$ and $x_i y_i^*$ commute. Then $x := x_1 \otimes x_2$ is a strong local minimum in $K_1 \otimes K_2$.

**Proof.** We show that under the hypotheses of the theorem, if $D^2_yH(x)$ is positive for every $y_i \in x_i^+$, then $D^2_yH(x)$ is positive for every $y \in x^+$. We break the proof into several cases depending on $y$.

First, suppose $y$ is a tensor product.

Case $y = x_1 \otimes y_2$, $y_2 \in x_2^+$: Since $y_2 \in x_2^+$ and $x_2$ is a strong local minimum, we know that

\[
a(x_2, y_2) + b(x_2, y_2) < c(x_2) - d(x_2, y_2).
\]

It is also easy to see from the expressions [5] that

\[
a(x_1, x_1) = b(x_1, x_1) = 1, \quad c(x_1) = d(x_1, x_1).
\]

So, using the expressions for tensors in [6], we have

\[
a(x, y) + b(x, y) = a(x_2, y_2) + b(x_2, y_2) \\
\leq c(x_2) - d(x_2, y_2) \\
= c(x) - d(x, y).
\]

Thus the second directional derivative is positive for this choice of $y$.

Case $y = y_1 \otimes x_2$, $y_1 \in x_1^+$: This case is similar to $y = x_1 \otimes y_2$.

Case $y = y_1 \otimes y_2$, $y_1, y_2 \in x_1^+$: Here we require the arithmetic-geometric mean inequality. For two terms $a_1, a_2 \leq 1$,

\[
a_1a_2 \leq \left( \frac{a_1 + a_2}{2} \right)^2 \leq \frac{1}{2}(a_1 + a_2).
\]

In particular, $a(x_1, x_1)a(x_2, y_2) \leq a(x_1, y_1) + a(x_2, y_2)$ and similarly for $b$. Now, since $y_i \in x_i^+$, we have $a(x_i, y_i) + b(x_i, y_i) < c(x_i) - d(x_i, y_i)$. Combining these inequalities we get $a(x, y) + b(x, y) \leq c(x) - d(x, y)$.

Next, we consider cases where $y$ is a linear combination of terms.

Suppose $y$ is in $x_1^+ \otimes x_2^+$. In this case, we break $y$ into two orthogonal pieces according to the projection matrix $P = x^*(xx^*)^{-1}x$. Let $P_i = x_i^*(x_i x_i^*)^{-1}x_i$: this is the projection matrix onto the range of $x_i^*$, which we denote $R(x_i^*)$. Then $P = P_1 \otimes P_2$ is the projection matrix onto the range $R(x^*) = R(x_1^*) \otimes R(x_2^*)$. Write $y$ as a direct sum:

\[
y = au + \beta v,
\]

where $u^* \in R(x_i^*)$ (so $Pu^* = u^*$), and $Pv^* = 0$. The normalizations are chosen so that $\alpha \in \mathbb{R}$ and $\beta \in \mathbb{R}$ satisfy $\alpha^2 + \beta^2 = 1$, and $\|u\|^2 = \|v\|^2 = 1$. We deal with the $u$ and $v$ components separately.

Case $y = u \in (x_1^+ \otimes x_2^+) \cap R(x_1^*)$: Here we have $b(x, u) = \|Pu\|^2 = \|u\|^2 = 1$. Note that if $y_i$ is in $x_i^+$, then

\[
\text{Tr}[x_i P_i y_i^*] = \text{Tr}[x_i x_i^*(x_i x_i^*)^{-1} x_i y_i^*] = \text{Tr}[x_i y_i^*] = 0,
\]

so $P_i y_i^*$ is also in $x_i^+$. If we write $u = \sum_j y_{ij} \otimes y_{2j}$ with $y_{ij} \in x_i^+$, then

\[
u = Pu = \sum_j P_1 y_{ij} \otimes P_2 y_{2j},
\]

then $P_i y_i^*$ is in $x_i^+ \cap R(x_i^*)$, and it follows that $u$ is in $(x_1^+ \cap R(x_1^*)) \otimes (x_2^+ \cap R(x_2^*))$. Now perform a Schmidt decomposition of $u$ with respect to this tensor space: we get

\[
u = \sum_j \alpha_j u_{1j} \otimes u_{2j},
\]

where $u_{ij} \in x_i^+ \cap R(x_i^*)$, $\text{Tr}[u_{ij}^* u_{jk}] = \delta_{jk}$, $\alpha_j \geq 0$, and $\sum_j \alpha_j^2 = 1$. Since $u_{ij}$ is in $R(x_i^*)$, we have $b(x_i, u_{ij}) = 1$. Since $u_{ij}$ is in $x_i^+$, we know

\[
a(x_i, u_{ij}) + b(x_i, u_{ij}) \leq c(x_i) - d(x_i, u_{ij}),
\]

and also $0 \leq a(x_i, u_{ij}) \leq 1$. Under this decomposition, we also have

\[
d(x, u) = \sum_j \alpha_j^2 (d(x_1, u_{1j}) + d(x_2, u_{2j})).
\]
Therefore, from (7) and (8),
\begin{align*}
a(x, u) + b(x, u) & \leq 2b(x, u) \\
& = \sum_j \alpha_j^2[b(x_1, u_{1,j}) + b(x_2, u_{1,2})] \\
& \leq \sum_j \alpha_j^2[c(x_1) - d(x_1, u_{1,j})] + c(x_2) - d(x_2, u_{1,2}) \\
& = c(x) - d(x, u).
\end{align*}

Case \( y = v \in x_1^\perp \otimes x_2^\perp \), \( P^x v = 0 \): We know that \( 0 \leq a(x, v) \leq b(x, v) = \| P^x v \| = 0 \), and so \( a(x, v) = b(x, v) = 0 \). Perform a Schmidt decomposition of \( v \) with respect to the space \( x_1^\perp \otimes x_2^\perp \):

\[ v = \sum_j \beta_j v_{ij} \otimes v_{2j}, \]

where \( v_{ij} \in x_1^\perp \), \( \text{Tr}(v_{ij} v_{jk}) = \delta_{jk} \) and \( \sum_j \beta_j^2 = 1 \). Since \( v_{ij} \) is in \( x_1^\perp \), we have \( 0 \leq a(x, v_{ij}) \leq b(x, v_{ij}) \) and

\[ 0 \leq a(x, v_{ij}) + b(x, v_{ij}) \leq c(x) - d(x, v_{ij}). \]

It follows quickly that \( a(x, v) + b(x, v) \leq c(x) - d(x, v) \).

Next we deal with a combination of \( u \) and \( v \). Consider \( y = v \in x_1^\perp \otimes x_2^\perp \), \( P^x v = 0 \), \( v^* \in R(x^*) \), \( P^x v^* = 0 \), \( \alpha^2 + \beta^2 = 1 \), and \( \| u \|^2 = \| v \|^2 = 1 \). Then since \( uu^* = uP^x v = 0 \), we have

\[ yy^* = \alpha^2 uu^* + \beta^2 vv^*, \]

from which it follows that

\begin{align*}
b(x, y) &= \alpha^2 b(x, u) + \beta^2 b(x, v), \\
d(x, y) &= \alpha^2 d(x, u) + \beta^2 d(x, v).
\end{align*}

(10) and (11) with the results for \( u \) and \( v \) from the previous cases, we get

\begin{align*}
a(x, y) + b(x, y) & \leq 2b(x, y) \\
& = \alpha^2 2b(x, u) + \beta^2 2b(x, v) \\
& \leq \alpha^2 [c(x) - d(x, u)] + \beta^2 [c(x) - d(x, v)] \\
& = c(x) - d(x, y).
\end{align*}

Finally, we have the case where \( y \) is an arbitrary element of \( x^\perp \).

Case \( y \in x^\perp \): Here \( y \) may be written in the form

\[ y = \alpha y_1 \otimes y_2 + \beta y_1 \otimes x_2 + \gamma y', \]

where \( y_1 \in x_1^\perp \) and \( y' \in x_1^\perp \otimes x_2^\perp \), with real constants satisfying \( \alpha^2 + \beta^2 + \gamma^2 = 1 \). Expanding out terms of \( yy^* \) and simplifying, we find that most terms disappear under trace:

\begin{align*}
d(x, y) &= \alpha^2 [c(x_1) + d(x_2, y_2)] + \beta^2 [c(x_2) + d(x_1, y_1)] \\
& + \gamma^2 d(x, y'), \\
b(x, y) &= \alpha^2 b(x_2, y_2) + \beta^2 b(x_1, y_1) + \gamma^2 b(x, y'), \\
a(x, y) &= \alpha^2 \text{Tr}[(x_2 x_2^*)^{-1} (x_2 y_2^*)^2] \\
& + \beta^2 \text{Tr}[(x_1 x_1^*)^{-1} (x_1 y_1^*)^2] + \gamma^2 \text{Tr}[(x x^*)^{-1} (x y y^*)^2].
\end{align*}

The expression for \( d(x, y) \) requires the observation that \( \text{Tr}[x_1 y_1^* \log(x_1 x_1^*)] = 0 \), because the first directional derivative of \( D_{x_1} H(x_1) \) is 0 when \( x_1 \) is a local minimum. The expression for \( a(x, y) \) is bounded as follows:

\begin{align*}
a(x, y) &= \alpha^2 \text{Tr}[(x_2 x_2^*)^{-1} (x_2 y_2^*)^2] \\
& + \beta^2 \text{Tr}[(x_1 x_1^*)^{-1} (x_1 y_1^*)^2] + \gamma^2 \text{Tr}[(x x^*)^{-1} (x y y^*)^2] \\
& \leq \alpha^2 \text{Tr}[(x_2 x_2^*)^{-1} (x_2 y_2^*)^2] \\
& + \beta^2 \text{Tr}[(x_1 x_1^*)^{-1} (x_1 y_1^*)^2] + \gamma^2 \text{Tr}[(x x^*)^{-1} (x y y^*)^2] \\
& = \alpha^2 a(x_2, y_2) + \beta^2 a(x_1, y_1) + \gamma^2 a(x, y').
\end{align*}

Combining (12), (13), and (15), we get \( a(x, y) + b(x, y) \leq c(x) - d(x, y) \).

\section*{IV. THE SECOND DERIVATIVE OF THE 2-NORM}

In this section we focus on the 2-norm since its second directional derivative has an elegant analytical form. We prove that if \( K_1 \) and \( K_2 \) are subspaces of matrices, at least one of which has dimension 2, and \( x_1 \in K_1 \), \( x_2 \in K_2 \) are strong local maxima of the 2-norm function

\[ x \mapsto \text{Tr}[(xx^*)^2] \]

subject to \( \text{Tr}[xx^*] = 1 \), then \( x_1 \otimes x_2 \) is also a strong local maximum in \( K_1 \otimes K_2 \). Since it is known that the 2-norm is not globally additive, this result sheds some light on the possibility that there exist functions that are locally additive while they are not globally additive.

We will work with the normalized function

\[ H_2(x) := \text{Tr} \left[ \frac{(xx^*)^2}{\| x \|^4} \right] = \frac{\text{Tr}[(xx^*)^2]}{\| x \|^2}. \]

As before, we consider \( (x + \epsilon y)(x + \epsilon y)^* = xx^* + \epsilon(xy^* + yx^*) + \epsilon^2(yyy^*) \), where \( \text{Tr}[xx^*] = \text{Tr}[yy^*] = 1 \) and \( \text{Tr}[xy^* + yx^*] = 0 \). Noting that

\begin{align*}
[(x + \epsilon y)(x + \epsilon y)^*]^2 &= (xx^*)^2 + 2xx^*yy^* + 2xx^*yx^* + 2yx^*yx^* + \mathcal{O}(\epsilon^3),
\end{align*}

and that \( \text{Tr}[(x + \epsilon y)(x + \epsilon y)^*]^2 = (1 + \epsilon^2)^2 \), we have that up to second order in \( \epsilon \),

\[ H_2(x + \epsilon y) = \text{Tr}[(xx^*)^2] + 2\epsilon \text{Tr}[xx^* (yx^* + yx^*)] + \mathcal{O}(\epsilon^3). \]

Finally, we have the case where \( y \) is an arbitrary element of \( x^\perp \).
Then the first directional derivative of $H_2$ is 
$$D_y H_2(x) = 2 \text{Tr}[xx^* (xy^* + yx^*)].$$
By considering $iy$ as well as $ye$, the condition $D_y H_2(x) = 0$ reduces to $\text{Tr}[xx^* y] = 0$. The second derivative is 
$$D_y^2 H_2(x) = 2 \text{Tr}[(xy^* + yx^*)^2] + 4 \text{Tr}[xx^* yy^*] - 4 \text{Tr}[(xx^*)^2].$$
For strong local maxima we expect $D_y^2 H_2(x)$ to be negative. Expand $(xy^* + yx^*)^2$ into four terms: then 
$$\text{Tr}[(xy^* + yx^*)^2] = 2 \text{Re} \text{Tr}[(xy^*)^2] + \text{Tr}[xx^* y^* y],$$
where $\text{Re}(z)$ denotes the real part of $z$. The largest value of $\text{Re} \text{Tr}[(xy^*)^2]$ over all choices of unit multiples of $y$ is $|\text{Tr}(yy^*)^2|$. In summary:

**Lemma 5.** Define $F(x, y) :=$
$$- \text{Tr}[(xx^*)^2] + |\text{Tr}(xy^*)^2| + \text{Tr}[xx^* yy^*] + \text{Tr}[xx^* y^* y].$$
Then $x$ is a strong local maximum of the function $x \mapsto \text{Tr}[(xx^*)^2]$, subject to $\text{Tr}[xx^*] = 1$, if and only if every $y \in x^1$, $\text{Tr}[yy^*] = 1$ satisfies $\text{Tr}[xx^* y^* y] = 0$ and $F(x, y) < 0$.

Denote the terms in $F(x, y)$ as follows:

$$a(x) := \text{Tr}[(xx^*)^2]$$
$$b(x, y) := |\text{Tr}(xy^*)^2|$$
$$c(x, y) := \text{Tr}[xx^* yy^*]$$
$$d(x, y) := \text{Tr}[xx^* y^* y].$$

The Cauchy-Schwartz inequality implies that $|\text{Tr}(z^2)| \leq \text{Tr}[z^* z]$ for any matrix $z$. Letting $z = xy^*$, we conclude that $0 \leq b(x, y) \leq c(x, y), d(x, y)$. Assuming $a > b + c + d$ therefore implies that $a > b, c, d$. Since $a = \text{Tr}[(xx^*)^2] \leq \text{Tr}[xx^*] = 1$, we see that each of the terms $a, b, c, d$ are in the range $[0, 1]$. Furthermore, each term is multiplicative under tensor products: $a(x_1 \otimes x_2) = a(x_1) a(x_2), b(x_1 \otimes x_2, y_1 \otimes y_2) = b(x_1, y_1) b(x_2, y_2)$, and so on.

From Section III, we know that for any $y$ critical points of the 2-norm are again critical points. We can now say the same for local maxima.

**Lemma 6.** Suppose $x_1$ and $x_2$ are strong local maxima of $x \mapsto \text{Tr}[(xx^*)^2]$ subject to $\text{Tr}[xx^*] = 1$ and $x_i \in K_i$, where either $K_1$ or $K_2$ has dimension 2. Then $x := x_1 \otimes x_2$ is a strong local maximum in $K_1 \otimes K_2$.

**Proof.** Without loss of generality, assume $K_1$ has dimension 2, so $x_1^1$ has dimension 1. Let $y_1$ be an element of $x_1^1$ and let $y_2$ be elements of $x_2^1$. Then every element of $x^2 \in K_1 \otimes K_2$ is a linear combination of vectors of the form $y_1 \otimes y_2, x_1 \otimes y_2$, and $y_1 \otimes x_2$. First, we check that for each $y$ of that form, $F(x, y)$ is negative.

Case $y = y_1 \otimes y_2$; Here

$$F(x, y) = -a(x_1) a(x_2) + (x_1, y_1) b(x_2, y_2) + c(x_1, y_1) c(x_2, y_2) + d(x_1, y_1) d(x_2, y_2).$$

Since $a(x_1) > (x_1, y_1) + c(x_1, y_1) + d(x_1, y_1)$ and each term is nonnegative, it follows that $a(x_1) a(x_2) > (x_1, y_1) b(x_2, y_2) + c(x_1, y_1) c(x_2, y_2) + d(x_1, y_1) d(x_2, y_2)$, and so $F(x, y)$ is negative.

**Case $y = x_1 \otimes y_2$:** Here

$$F(x, y) = -a(x_1) a(x_2) + (x_1, y_1) b(x_2, y_2) + c(x_1, y_1) c(x_2, y_2) + d(x_1, y_1) d(x_2, y_2).$$

But $-a(x_2) + b(x_2, y_2) + c(x_2, y_2) + d(x_2, y_2) < 0$ and $a(x_1) > 0$, so $F(x, y)$ is negative.

Case $y = y_1 \otimes x_2$: Similar to $y = x_1 \otimes y_2$.

Now consider a linear combination of the three elements of $x^1$, say

$$y = \alpha(y_1 \otimes y_2) + \beta(x_1 \otimes y_2) + \gamma(x_1 \otimes x_2).$$

In considering $b(x, y)$, most terms disappear under trace:

$$b(x, y) = |\alpha^2 \text{Tr}[(x_1 y_1^*)^2] \text{Tr}[(x_2 y_2^*)^2]|$$
$$+ \beta^2 \text{Tr}[(x_1 x_2^*)^2] \text{Tr}[(x_2 y_2^*)^2] + \gamma^2 \text{Tr}[(x_1 y_1^*)^2] \text{Tr}[(x_2 x_2^*)^2]$$
$$\leq |\alpha|^2 b(x_1, y_1) b(x_2, y_1)$$
$$+ |\beta|^2 a(x_1) b(x_2, y_2) + |\gamma|^2 b(x_1, y_1) a(x_2).$$

Likewise we have

$$c(x, y) = |\alpha|^2 c(x_1, y_1) c(x_2, y_2) +$$
$$|\beta|^2 a(x_1) c(x_2, y_2) + |\gamma|^2 c(x_1, y_1) a(x_2),$$

and similarly for $d(x, y)$. Adding together, we conclude that

$$F(x, y) \leq |\alpha|^2 [-a(x_1) a(x_2) + (x_1, y_1) b(x_2, y_2) + c(x_1, y_1) c(x_2, y_2) + d(x_1, y_1) d(x_2, y_2)]$$
$$+ |\beta|^2 a(x_1) [-a(x_2) + b(x_2, y_2) + c(x_2, y_2) + d(x_2, y_2)]$$
$$+ |\gamma|^2 [-a(x_1) + b(x_1, y_1) + c(x_1, y_1) + d(x_1, y_1)] a(x_2).$$

The $|\alpha|^2$ term is negative by the argument given in the case $y = y_1 \otimes y_2$; the $|\beta|^2$ term is negative by the case $y = x_1 \otimes y_2$; and the $|\gamma|^2$ term is negative by the case $y = y_1 \otimes x_2$. $\square$

If both $K_1$ and $K_2$ have dimension higher than 2, the linear combinations seem to be more difficult.

We appreciate many valuable discussions with Jon Yard. Research by GG and AR was supported by NSERC, PIMS, and iCORE.
Appendix A: Affine parametrization

Let $x \in K \subset \mathbb{C}^{m \times n}$ and assume that $xx^* > 0$, i.e. $xx^*$ invertible, and $\text{Tr} xx^* = 1$. When now study the second variation. Let $y \in K$ and assume that $\text{Tr}(xy^* + yx^*) = 0$. We then consider

$$A(e) := A + eB + e^2 C = (x + ey)(x + ey)^*;$$
$$A = xx^*, B = xy^* + yx^*, C = yy^* \in H_m.$$ (A1)

(Here $H_m$ is the real space of $m \times m$ matrices.) Let $\lambda_1(e), \ldots, \lambda_m(e) > 0$ be the eigenvalues of $A(e)$, as analytic functions of $e$, (Rellich’s theorem [5]). We can assume that these eigenvalues are arranged in the following order $\lambda_1(e) \geq \ldots \geq \lambda_m(e) > 0$ for small positive $e$. Let $A_1(e) = A + eB$. Arrange the analytic eigenvalues of $A_1(e)$ in the order $\mu_1(e) \geq \ldots \geq \mu_m(e) > 0$ for small positive $e$. Clearly, $\lambda_i(e) = \mu_i(e) + O(e^2)$ for $i = 1, \ldots, m$.

The following result is known, and can be deduced from the arguments in Kato [5].

Lemma 7. Let $A, B, C \in H_m$, and denote $A(e) = A + eB + e^2 C, A_1(e) = A + eB$. Assume that $\lambda_1(e), \ldots, \lambda_m(e)$ and $\mu_1(e), \ldots, \mu_m(e)$ are analytic eigenvalues of $A_1(e), A_1(e)$ arranged in a nonincreasing order for small positive $e$. Then, there exists a unitary matrix $U \in \mathbb{C}^{m \times m}$ with the following two properties. First, $UAU^* = \text{diag} (\lambda_1, \ldots, \lambda_m)$. Second, if we denote $UCU^* \equiv F = |f_{ij}|_{i,j=1}^m$ then

$$\lambda_i(e) = \mu_i(e) + e^2 f_{ii} + O(e^3)$$ for $i = 1, \ldots, m$. (A2)

In the next proposition we use the above lemma to calculate the variation of $S(A) = -\text{Tr}(A \log A)$ up to second order.

Proposition 1. Let $x, y \in \mathbb{C}^{m \times n}$ and assume that $\text{Tr}(xx^*) = \text{Tr}(yy^*) = 1, xx^* > 0, \text{Tr}(xy^* + yx^*) = 0$. Define $A(e), A_1(e)$ as in Eq. (A1). Then

$$S \left( \frac{A(e)}{\text{Tr} A(e)} \right) = S(A_1(e)) + e^2 \text{Tr}[(xx^* - yy^*) \log xx^*] + O(e^3)$$ (A3)

Proof. First recall that

$$S \left( \frac{A(e)}{\text{Tr} A(e)} \right) = \frac{1}{\text{Tr} A(e)} S(A(e)) + \log \text{Tr} A(e)$$
$$= S(A(e)) + e^2 \left[ -\text{Tr}(yy^*) S(xx^* + \text{Tr}(yy^*)) \right] + O(e^3).$$ (A4)

Next we claim

$$S(A(e)) = - \sum_{i=1}^m \lambda_i(e) \log \lambda_i(e)$$
$$= - \sum_{i=1}^m (\mu_i(e) + f_{ii} e^2) \log(\mu_i(e) + f_{ii} e^2) + O(e^3) =$$
$$- \sum_{i=1}^m \mu_i(e) \log \mu_i(e) - e^2 \sum_{i=1}^m f_{ii} \log \lambda_i + \sum_{i=1}^m f_{ii} + O(e^3)$$
$$= S(A_1(e)) - e^2 (\text{Tr}((yy^*) \log(xx^*)) + \text{Tr}(yy^*)) + O(e^3).$$

Combine this expression with the expression above it to deduce [A3].

Note that the expression $\text{Tr}[(xx^* - yy^*) \log xx^*]$ can be either positive or negative. In the following we give a very simple reason why we can not ignore this term (i.e. use the affine approximation), which also yields a necessary condition $xx^*$ must satisfy if $x$ is a local minimum.

Assume that we have an affine subspace of the form $A + tB$, where $\text{Tr}(A) = 1, \text{Tr}(B) = 0$. Here $A = xx^*, B = xy^* + yx^*$ on all $y \in K$ satisfying the condition $\text{Tr}(B) = 0$ and $t$ arbitrary real. Let $\Phi$ be the set of all $A + tB$ such that $A + tB \geq 0$. Consider the function $S(C) = -\text{Tr}(C \log C)$ where $C \in \Phi$. Our assumption that $A$ is a critical point in $\Phi$ for the $S(C)$. Since $S(C)$ is strictly concave on $\Phi$ it follows that $A$ is a unique global maximum on $\Phi$. So if $A$ was a local minimum for the $H(x), x \in K, \text{Tr}(xx^*) = 1$ it follows that the correction term for $e^2$ that we have must be strictly positive. That is, if $x$ is a local min then

$$\text{Tr}[(xx^* - yy^*) \log xx^*] = S(yy^*) - S(xx^*) + S(yy^*) ||xx^*) > 0$$

for all $y \in x^\perp$ (assuming the normalization $\text{Tr}(yy^*) = 1$).

Appendix B: A counterexample to real additivity conjecture

During the 2008 American Institute for Mathematics workshop “Geometry and representation theory” [4], Leonid Gurvits found a counterexample to the analogue of the additivity conjecture for real (rather than complex) matrices. In this appendix we generalize the counterexample to show that the additivity conjecture fails to hold for real spaces of orthogonal matrices containing the identity: there exist real subspaces $K_1 \subseteq \mathbb{R}^{m_1 \times n_1}$ and $K_2 \subseteq \mathbb{R}^{m_2 \times n_2}$ such that $H(K_1 \otimes K_2) < H(K_1) + H(K_2)$. $K \subseteq \mathbb{R}^{m \times n}$ is called an orthogonal subspace if any $0 \neq A \in K$ is of the form $aQ$ for some scalar $a$ and an orthogonal matrix $Q$. Note that if $K$ is an orthogonal subspace then for any orthogonal matrix $Q_0$, the subspace $Q_0^\perp K$ is also an orthogonal subspace. By choosing $Q_0 \in K$ we can always assume that $K$ contains the identity matrix $I_m$.

The maximal size of an orthogonal subspace is given by the Radon-Hurwitz number, defined as follows. For $m \in \mathbb{N}$, let $m = 2^k \cdot a$, with $a$ odd, and let $b = 4c + d$ where $c$ is a nonnegative integer and $d \in \{0, 1, 2, 3\}$. Then Radon-Hurwitz number of $m$ is $\rho(m) := 2^d + 8c$.

Theorem 3. Let $K \subseteq \mathbb{R}^{m \times n}$ be an orthogonal subspace. Then $k := \dim K \leq \rho(m)$, and this inequality is sharp for any $m \in \mathbb{N}$. More precisely, assume that $I_m \in K$ and $k \geq 2$. Then $K$ has a basis $I_m, Q_1, \ldots, Q_{k-1}$ where $Q_1, \ldots, Q_{k-1}$ is a set of skew symmetric orthogonal anticommuting matrices, i.e. $Q_i Q_j = -Q_j Q_i$ for any $1 \leq i < j \leq k-1$. 

Conversely, if $Q_1, \ldots, Q_{k-1} \in \mathbb{R}^{m \times m}$ are $k-1$ skew symmetric orthogonal anticommuting matrices then $\text{span}(I_m, Q_1, \ldots, Q_{k-1})$ is an $k$-dimensional orthogonal subspace.

If $Q \in \mathbb{R}^{m \times m}$ is an orthogonal matrix, then all $m$ singular values of $Q$ are equal to $1$. Furthermore, let $Q_1, Q_2 \in \mathbb{R}^{m \times m}$ be an orthogonal matrix for $i = 1, 2$. Then for any real $a_1, a_2$, the singular values of $a_1 Q_1 a_2 Q_2$, the singular values of $a_1 Q_1 a_2 Q_2$, are skew symmetric orthogonal matrices. Then $a_1 Q_1$ has $\frac{m}{2}$ eigenvalues equal to $a_1 \sqrt{-1}$ and $-a_1 \sqrt{-1}$ for $i = 1, 2$ respectively. Furthermore, $(a_1 Q_1) \otimes (a_2 Q_2)$ is a real symmetric matrix with $\frac{m}{2}m$ eigenvalues equal to $a_1 a_2$ and $\frac{m}{2}m$ eigenvalues equal to $-a_1 a_2$.

**Theorem 4.** Let $K \subseteq \mathbb{R}^{m \times m}$ be an orthogonal subspace. Then $H(K) = \log m$.

Suppose furthermore that $m_1, m_2$ are even and $K_i \in \mathbb{R}^{m_i \times m_i}$ are orthogonal subspaces of dimension two at least for $i = 1, 2$. Then

$$H(K_1 \otimes K_2) \leq \log \frac{m_1 m_2}{2} = \log(m_1 m_2) - \log 2$$

$$= H(K_1) + H(K_2) - \log 2 \quad (B1)$$

In particular, the additivity conjecture does not hold for real subspaces of matrices.

**Proof.** Since any matrix $x \in K$ is of the form $aQ$ for some orthogonal $Q$ it follows that if $\text{Tr}(xx^\top) = 1$ then the singular values of $x$ are all equal to $\frac{1}{m}$. Hence $H(x) = \log m$ and $H(K) = \log m$.

Assume now that $K_1, K_2$ are orthogonal spaces of dimension two at least. Without loss of generality we may assume that $I_{m_1}, Q_1 \in \mathbb{R}^{m_1 \times m_1}$ and $I_{m_2}, Q_2 \in \mathbb{R}^{m_2 \times m_2}$, where $Q_1, Q_2$ are orthogonal. Hence $I_{m_1 m_2} = I_{m_1} \otimes I_{m_2}$ and $Q_1 \otimes Q_2$ are both in $K_1 \otimes K_2$. Recall that $Q_1 \otimes Q_2$ is a symmetric matrix which has $\frac{m_1 m_2}{2}$ eigenvalues equal to $1$ and $-1$ respectively. Hence $Q_1 \otimes Q_2 + I_{m_1 m_2}$ is a nonnegative definite real symmetric matrices which has $\frac{m_1 m_2}{2}$ eigenvalues equal to $2$ and $0$ respectively. Let $x = (\frac{2}{m_1 m_2})^{\frac{1}{2}}(Q_1 \otimes Q_2 + I_{m_1 m_2})$. Then $\text{Tr}(xx^\top) = 1$ and $x$ has $\frac{m_1 m_2}{2}$ nonzero singular values all equal to $\frac{2}{m_1 m_2}$. Hence $H(K_1 \otimes K_2) \leq H(x) = \log(\frac{m_1 m_2}{2})$.
