

## Types and Static Semantic Analysis

COMS W4115

Prof. Stephen A. Edwards  
Spring 2007  
Columbia University  
Department of Computer Science

## C's Types: Base Types/Pointers

Base types match typical processor

<b>Typical sizes:</b>	8	16	32	64
	char	short	int	long
			float	double

Pointers (addresses)

```
int *i; /* i is a pointer to an int */
char **j; /* j is a pointer to
a pointer to a char */
```

## Data Types

What is a type?

A *restriction on the possible interpretations of a segment of memory or other program construct.*

Useful for two reasons:

Runtime optimization: earlier binding leads to fewer runtime decisions. E.g., Addition in C efficient because type of operands known.

Error avoidance: prevent programmer from putting round peg in square hole. E.g., In Java, can't open a complex number, only a file.

## Are Data Types Necessary?

No: many languages operate just fine without them.

Assembly languages usually view memory as undifferentiated array of bytes. Operators are typed, registers may be, data is not.

Basic idea of stored-program computer is that programs be indistinguishable from data.

Everything's a string in Tcl including numbers, lists, etc.

## C's Types: Arrays, Functions

Arrays

```
char c[10]; /* c[0] ... c[9] are chars */
double a[10][3][2]; /* array of 10
arrays of 3 arrays
of 2 doubles */
```

Functions

```
/* function of two arguments
returning a char */
char foo(int, double);
```

## C's Types: Structs and Unions

Structures: each field has own storage

```
struct box {
int x, y, h, w;
char *name;
};
```

Unions: fields share same memory

```
union token {
int i;
double d;
char *s;
};
```

## Composite Types: Records

A record is an object with a collection of fields, each with a potentially different type. In C,

```
struct rectangle {
int n, s, e, w;
char *label;
color col;
struct rectangle *next;
};
```

```
struct rectangle r;
r.n = 10;
r.label = "Rectangle";
```

## Composite Types: Variant Records

A record object holds all of its fields. A variant record holds only one of its fields at once. In C,

```
union token {
int i;
float f;
char *string;
};
```

```
union token t;
t.i = 10;
t.f = 3.14159; /* overwrites t.i */
char *s = t.string; /* returns gibberish */
```

## Applications of Records

Records are the precursors of objects:

Group and restrict what can be stored in an object, but not what operations they permit.

Can fake object-oriented programming:

```
struct poly { ... };

struct poly *poly_create();
void poly_destroy(struct poly *p);
void poly_draw(struct poly *p);
void poly_move(struct poly *p, int x, int y);
int poly_area(struct poly *p);
```

## Applications of Variant Records

A primitive form of polymorphism:

```
struct poly {
    int x, y;
    int type;
    union { int radius;
            int size;
            float angle; } d;
};
```

If `poly.type == CIRCLE`, use `poly.d.radius`.

If `poly.type == SQUARE`, use `poly.d.size`.

If `poly.type == LINE`, use `poly.d.angle`.

## Layout of Records and Unions

Slower to read an unaligned value: two reads plus shift.

SPARC prohibits unaligned accesses.

MIPS has special unaligned load/store instructions.

x86, 68k run more slowly with unaligned accesses.

## C's Type System

Types may be intermixed at will:

```
struct {
    int i;
    union {
        char (*one)(int);
        char (*two)(int, int);
    } u;
    double b[20][10];
} *a[10];
```

Array of ten pointers to structures. Each structure contains an int, a 2D array of doubles, and a union that contains a pointer to a char function of one or two arguments.

## Layout of Records and Unions

Modern processors have byte-addressable memory.

0
1
2
3
4

Many data types (integers, addresses, floating-point numbers) are wider than a byte.

16-bit integer: 

1	0
---	---

32-bit integer: 

3	2	1	0
---	---	---	---

## Layout of Records and Unions

Most languages "pad" the layout of records to ensure alignment restrictions.

```
struct padded {
    int x; /* 4 bytes */
    char z; /* 1 byte */
    short y; /* 2 bytes */
    char w; /* 1 byte */
};
```

## Strongly-typed Languages

Strongly-typed: no run-time type clashes.

C is definitely not strongly-typed:

```
float g;
union { float f; int i } u;
u.i = 3;
g = u.f + 3.14159; /* u.f is meaningless */
```

Is Java strongly-typed?

## Layout of Records and Unions

Modern memory systems read data in 32-, 64-, or 128-bit chunks:

3	2	1	0
7	6	5	4
11	10	9	8

Reading an aligned 32-bit value is fast: a single operation.

3	2	1	0
7	6	5	4
11	10	9	8

## C's Type System: Enumerations

```
enum weekday {sun, mon, tue, wed,
              thu, fri, sat};
```

```
enum weekday day = mon;
```

Enumeration constants in the same scope must be unique:

```
enum days {sun, wed, sat};
```

```
enum class {mon, wed}; /* error: mon, wed
                       redefined */
```

## Statically-Typed Languages

Statically-typed: compiler can determine types.

Dynamically-typed: types determined at run time.

Is Java statically-typed?

```
class Foo {
    public void x() { ... }
}
class Bar extends Foo {
    public void x() { ... }
}
void baz(Foo f) {
    f.x();
}
```

## Polymorphism

Say you write a sort routine:

```
void sort(int a[], int n)
{
    int i, j;
    for ( i = 0 ; i < n-1 ; i++ )
        for ( j = i + 1 ; j < n ; j++ )
            if (a[j] < a[i]) {
                int tmp = a[i];
                a[i] = a[j];
                a[j] = tmp;
            }
}
```

## Polymorphism

To sort doubles, only need to change a few types:

```
void sort(double a[], int n)
{
    int i, j;
    for ( i = 0 ; i < n-1 ; i++ )
        for ( j = i + 1 ; j < n ; j++ )
            if (a[j] < a[i]) {
                double tmp = a[i];
                a[i] = a[j];
                a[j] = tmp;
            }
}
```

## C++ Templates

```
template <class T> void sort(T a[], int n)
{
    int i, j;
    for ( i = 0 ; i < n-1 ; i++ )
        for ( j = i + 1 ; j < n ; j++ )
            if (a[j] < a[i]) {
                T tmp = a[i];
                a[i] = a[j];
                a[j] = tmp;
            }
}

int a[10];
sort<int>(a, 10);
```

## C++ Templates

C++ templates are essentially language-aware macros. Each instance generates a different refinement of the same code.

```
sort<int>(a, 10);

sort<doubles>(b, 30);

sort<char *>(c, 20);

Fast code, but lots of it.
```

## Faking Polymorphism with Objects

```
class Sortable {
    bool lessthan(Sortable s) = 0;
}

void sort(Sortable a[], int n) {
    int i, j;
    for ( i = 0 ; i < n-1 ; i++ )
        for ( j = i + 1 ; j < n ; j++ )
            if ( a[j].lessthan(a[i]) ) {
                Sortable tmp = a[i];
                a[i] = a[j];
                a[j] = tmp;
            }
}
```

## Faking Polymorphism with Objects

This sort works with any array of objects derived from Sortable.

Same code is used for every type of object.

Types resolved at run-time (dynamic method dispatch).

Does not run as quickly as the C++ template version.

## Arrays

Most languages provide array types:

```
char i[10]; /* C */

character(10) i ! FORTRAN

i : array (0..9) of character; -- Ada

var i : array [0 .. 9] of char; { Pascal }
```

## Array Address Calculation

In C,  
struct foo a[10];  
a[i] is at  $a + i * \text{sizeof}(\text{struct foo})$   
struct foo a[10][20];  
a[i][j] is at  $a + (j + 20 * i) * \text{sizeof}(\text{struct foo})$   
⇒ Array bounds must be known to access 2D+ arrays

## Allocating Arrays

```
int a[10]; /* static */

void foo(int n)
{
    int b[15]; /* stacked */
    int c[n]; /* stacked: tricky */
    int d[]; /* on heap */
    vector<int> e; /* on heap */

    d = new int[n*2]; /* fixes size */
    e.append(1); /* may resize */
    e.append(2); /* may resize */
}
```

## Allocating Fixed-Size Arrays

Local arrays with fixed size are easy to stack.

## Allocating Variable-Sized Arrays

Variable-sized local arrays aren't as easy.

Doesn't work: generated code expects a fixed offset for `c`.  
Even worse for multi-dimensional arrays.

## Allocating Variable-Sized Arrays

As always:  
add a level of indirection

```
void foo(int n)
{
    int a;
    int b[n];
    int c;
}
```

Variables remain constant offset from frame pointer.

## Static Semantic Analysis

Lexical analysis: Make sure tokens are valid

```
if i 3 "This" /* valid */
#a1123 /* invalid */
```

Syntactic analysis: Makes sure tokens appear in correct order

```
for i := 1 to 5 do 1 + break /* valid */
if i 3 /* invalid */
```

Semantic analysis: Makes sure program is consistent

```
let v := 3 in v + 8 end /* valid */
let v := "f" in v(3) + v end /* invalid */
```

## Name vs. Structural Equivalence

```
typedef struct { int x, y; } foo;
typedef struct { int x, y; } bar;
typedef bar baz;
```

```
foo a = { 1, 2 }, c = { 4, 5 };
bar b = { 3, 4 };
baz d = { 5, 6 };
```

```
void baz() {
    c = a; /* Is this OK? */
    b = d; /* Is this OK? */
    b = a; /* Is this OK? */
}
```

## Static Semantic Analysis

### Name vs. Structural Equivalence

```
typedef struct { int x, y; } foo;
typedef struct { int x, y; } bar;
typedef bar baz;

foo a = { 1, 2 }, c = { 4, 5 };
bar b = { 3, 4 };
baz d = { 5, 6 };

void baz() {
    c = a; /* OK: both foo */
    b = d; /* OK: baz an alias for bar */
    b = a; /* Bad: foo not the same as bar */
}
```

### Things to Check

- Used identifiers must be defined
- Function calls must refer to functions
- Identifier references must be to variables
- The types of operands for unary and binary operators must be consistent.
- The first expression in an `if` and `while` must be a Boolean.
- It must be possible to assign the type on the right side of an assignment to the lvalue on the left.
- ...

### Things to Check

Make sure variables and functions are defined.

```
int i;
i(10,20); /* Error: i is a variable, not function */
```

Verify each expression's types are consistent.

```
int i = 10;
char *s = "Hello";

i + j /* Error: i is int, j is string */
```

## Static Semantic Analysis

Basic paradigm: recursively check AST nodes.

```
1 + break          1 - 5
 $\int$  break         $\sqrt{1}$  5
check(+)          check(-)
check(1) = int    check(1) = int
check(break) = void  check(5) = int
FALL: int  $\neq$  void  Types match, return int
```

Ask yourself: at a particular node type, what must be true?

## Type Classes

```
package Semant;
public abstract class Type {
    public Type actual()
    public boolean coerceTo(Type t)
}

public INT() // int
public STRING() // string
public NIL() // nil
public VOID() // ()
public NAME(String n) // type a = b
public ARRAY(Type e) // array of int
```

## Symbol Tables

```
package Semant;

public class Table {
    public Table()
    public Object get(String key)
    public void put(String key, Object value)
    public void enterScope()
    public void leaveScope()
}
```

## Implementing Static Semantics

Recursive walk over the AST.

Analysis of a node returns its type or signals an error.

Implicit "environment" maintains information about what symbols are currently in scope.

```
expr returns [Type t]
{ Type a, b, c; t = env.getVoidType(); }
: "nil" { t = env.getNilType(); }
| t=Ivalue
| STRING { t = env.getStringType(); }
| NUMBER { t = env.getIntType(); }
| #( NEG a=expr
    { /* Verify expr is an int */
      if ( !(a instanceof Semant.INT) )
        semantError("#expr,
                    \"Operand not integer\"");
      t = env.getIntType();
    }
  )
}
```

## Environment.java

```
package Semant;

public class Environment {
    public Table vars = new Table();
    public Table types = new Table();
    public INT getIntType()
    public VOID getVoidType()
    public NIL getNilType()
    public STRING getStringType()

    public void enterScope()
    public void leaveScope()
}
```

coerceTo() answers the "can this be assigned to" question.

```
typedef struct { int x; } a;
typedef b a;

nil.coerceTo(a) is true
b.coerceTo(a) is true
a.coerceTo(nil) is false
```

## Symbol Tables

Operations:

put(String key, Object value) inserts a new named object in the table, replacing any existing one in the current scope.

Object get(String key) returns the object of the given name, or null if there isn't one.

## Symbol Table Scopes

void enterScope() pushes a new scope on a stack.  
void leaveScope() removes the topmost one.

```
Table t = new Table();
t.put("a", new VarEntry(env.getIntType()));
t.put("a", new VarEntry(env.getStringType()));
t.get("a"); // string
t.enterScope();
t.get("a"); // string
t.put("a", new VarEntry(env.getIntType()));
t.get("a"); // int
t.leaveScope();
t.get("a"); // string
```

## Symbol Table Objects

Discriminates between variables and functions.

Stores extra information for each.

```
package Semant;  
  
public VarEntry(Type t)  
public FunEntry(Args f, Type r)
```

## Symbol Tables and the Environment

The environment has two symbol tables:

- types for types  
Objects stored in symbol table are Types
- vars for variables and functions  
Objects are VarEntries and FunEntries.

## Rule for an Identifier

```
lvalue returns [Type t]  
{ Type a, b; t = env.getVoidType(); }  
  
: i:ID {  
    Entry e = (Entry) env.vars.get(i.getText());  
    if ( e == null )  
        semantError(i, i.getText()+" undefined");  
    if ( !(e instanceof VarEntry) )  
        semantError(i, i.getText()+" not variable");  
    VarEntry v = (VarEntry) e;  
    t = v.ty;  
}
```

## Rule for a C-style Block

```
| #( BLOCK  
  { env.enterScope(); }  
  #(DECLS ( #(DECLS ( decl)+ )))* )  
  a=expr  
  {  
    env.leaveScope();  
    t = a;  
  }  
)
```

## Variable Declaration

```
decl { Type a, b; }  
: #( DECL a=type i:ID b=expr  
  {  
    /* Verify type of b is a */  
    env.vars.put(i.getText(), new VarEntry(b));  
  }  
)
```

## Partial rule for BINOP

```
| #( BINOP a=expr b=expr {  
  String op = #expr.getText();  
  if ( op.equals("+") || op.equals("-") ||  
      op.equals("*") || op.equals("/") ) {  
    if ( !(a instanceof Semant.INT) ||  
        !(b instanceof Semant.INT) )  
        semantError("#expr, op+" operands not int");  
    t = a;  
  } else {  
    /* Check other operators */  
  }  
)
```
