Outline

Goal: Unify and generalize existing algebras by defining families of Hecke-like algebras depending on Frobenius algebras.

Overview:

- 1 Strict monoidal categories and string diagrams
- 2 Warm up: symmetric groups, degenerate affine Hecke algebras
- 3 Frobenius algebras
- 4 Affine wreath product algebras
- 5 Quantum affine wreath algebras

Strict monoidal categories

A **strict monoidal category** is a category \mathcal{C} equipped with

- a bifunctor (the **tensor product**) $\otimes: \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$, and
- a **unit object** $\mathbb{1}$,

such that

- $(A \otimes B) \otimes C = A \otimes (B \otimes C)$ for all objects A, B, C ,
- $\mathbb{1} \otimes A = A = A \otimes \mathbb{1}$ for all objects A .

Remark: Non-strict monoidal categories

In a (not necessarily strict) **monoidal category**, the equalities above are replaced by isomorphism, and we impose some **coherence conditions**.

Every monoidal category is monoidally equivalent to a strict one.

\mathbb{k} -linear monoidal categories

Fix a commutative ground ring \mathbb{k} .

A **strict \mathbb{k} -linear monoidal category** is a strict monoidal category such that

- each morphism space is a \mathbb{k} -module,
- composition of morphisms is \mathbb{k} -bilinear,
- tensor product of morphisms is \mathbb{k} -bilinear.

The interchange law

The axioms of a strict monoidal category imply the **interchange law**: For $A_1 \xrightarrow{f} A_2$ and $B_1 \xrightarrow{g} B_2$, the following diagram commutes:

$$\begin{array}{ccc} A_1 \otimes B_1 & \xrightarrow{1 \otimes g} & A_1 \otimes B_2 \\ f \otimes 1 \downarrow & \searrow f \otimes g & \downarrow f \otimes 1 \\ A_2 \otimes B_1 & \xrightarrow{1 \otimes g} & A_2 \otimes B_2 \end{array}$$

String diagrams

Fix a strict monoidal category \mathcal{C} .

We will denote a morphism $f: A \rightarrow B$ by:

The **identity map** $1_A: A \rightarrow A$ is a string with no label:

We sometimes omit the object labels when they are clear or unimportant.

String diagrams

Composition is **vertical stacking** and tensor product is **horizontal juxtaposition**:

The **interchange law** then becomes:

A morphism $f: A_1 \otimes A_2 \rightarrow B_1 \otimes B_2$ can be depicted:

Presentations of strict monoidal categories

One can give **presentations** of some strict \mathbb{k} -linear monoidal categories, just as for monoids, groups, algebras, etc.

Objects: If the objects are generated by some collection $A_i, i \in I$, then we have all possible tensor products of these objects:

$$\mathbb{1}, \quad A_i, \quad A_i \otimes A_j \otimes A_k \otimes A_\ell, \quad \text{etc.}$$

Morphisms: If the morphisms are generated by some collection $f_j, j \in J$, then we have all possible compositions and tensor products of these morphisms (whenever these make sense):

$$1_{A_i}, \quad f_j \otimes (f_i f_k) \otimes (f_\ell), \quad \text{etc.}$$

We then often impose some **relations** on these morphism spaces.

String diagrams: We can build complex diagrams out of our simple generating diagrams.

The symmetric group category

Define a strict \mathbb{k} -linear monoidal category $\mathcal{S}ym$ with one generating object \uparrow and denote

$$1_{\uparrow} = \uparrow$$

We have one generating morphism

$$\begin{array}{c} \nearrow \\ \searrow \end{array} : \uparrow \otimes \uparrow \rightarrow \uparrow \otimes \uparrow.$$

We impose the relations:

$$\begin{array}{c} \nearrow \\ \searrow \\ \nearrow \\ \searrow \end{array} = \begin{array}{c} \uparrow \\ \uparrow \end{array}, \quad \begin{array}{c} \nearrow \\ \searrow \\ \nearrow \\ \searrow \end{array} = \begin{array}{c} \nearrow \\ \searrow \\ \searrow \\ \nearrow \end{array}.$$

Then

$$\text{End}_{\mathcal{S}ym}(\uparrow^{\otimes n}) = \mathbb{k}S_n$$

is the group algebra of the **symmetric group** on n letters.

The symmetric group category

This monoidal presentation of $\mathbb{k}S_n$ is very efficient! We only needed

- one generating morphism, and
- two relations,

to get **all** the symmetric groups.

Note that the “distant braid relation”

$$s_i s_j = s_j s_i, \quad |i - j| > 1$$

for simple transpositions follows for free from the interchange law:

Degenerate affine Hecke algebras

The degenerate affine Hecke algebra H_n of type A is

$$\mathbb{k}[x_1, \dots, x_n] \otimes \mathbb{k}S_n$$

as a \mathbb{k} -module.

The factors $\mathbb{k}[x_1, \dots, x_n]$ and $\mathbb{k}S_n$ are subalgebras, and

$$\begin{aligned} s_i x_j &= x_j s_i, & j &\neq i, i+1, \\ s_i x_i &= x_{i+1} s_i - 1. \end{aligned}$$

String diagrams

Obtain \mathcal{H} from Sym by adjoining one additional morphism (a **dot**)

$$\uparrow^{\circ} : \uparrow \rightarrow \uparrow$$

and one additional relation:

$$\begin{array}{c} \swarrow \circ \searrow \\ \times \\ \swarrow \searrow \circ \end{array} - \begin{array}{c} \swarrow \searrow \\ \times \\ \swarrow \circ \searrow \end{array} = \uparrow \uparrow .$$

Then

$$\text{End}_{\mathcal{H}}(\uparrow^{\otimes n}) = H_n$$

Frobenius algebras

Definition (symmetric Frobenius algebra)

An associative algebra A together with a linear **trace map**

$$\mathrm{tr}: A \rightarrow \mathbb{k}, \quad \mathrm{tr}(ab) = \mathrm{tr}(ba),$$

such that $\ker \mathrm{tr}$ contains no nonzero left ideals.

Example (\mathbb{k})

\mathbb{k} with $\mathrm{tr} = \mathrm{id}_{\mathbb{k}}$.

Example ($\mathbb{k}[x]/(x^k)$)

$\mathbb{k}[x]/(x^k)$ with $\mathrm{tr}(x^\ell) = \delta_{\ell, k-1}$.

Example (Matrix algebra)

Matrix algebras with the usual trace.

Frobenius algebras: Examples

Example (Group algebra)

If G is a finite group, then the **group algebra** $\mathbb{k}G$ is a Frobenius algebra with

$$\mathrm{tr}(g) = \delta_{g,1_G}, \quad g \in G.$$

Example (Hopf algebras)

Every f.d. Hopf algebra is a Frobenius algebra.

From now on: A is a symmetric Frobenius algebra with trace tr .

Remark: Can actually work more generally, with graded Frobenius superalgebras (not necessarily symmetric).

Wreath product algebras

The symmetric group S_n acts on $A^{\otimes n}$ by **permutations**:

$$\pi(a_n \otimes \cdots \otimes a_1) = a_{\pi^{-1}(n)} \otimes \cdots \otimes a_{\pi^{-1}(1)},$$

Wreath product algebra

The **wreath product algebra** is

$$\mathrm{Wr}_n(A) = A^{\otimes n} \otimes \mathbb{k}S_n$$

as \mathbb{k} -modules. Multiplication is determined by

$$(\mathbf{a} \otimes \pi)(\mathbf{b} \otimes \sigma) = \mathbf{a}\pi(\mathbf{b}) \otimes \pi\sigma.$$

Wreath product algebras: Examples

Example ($A = \mathbb{k}$)

$$\mathrm{Wr}_n(\mathbb{k}) \cong \mathbb{k}S_n$$

Example ($A = \mathrm{Cl}$)

$\mathrm{Wr}_n(\mathrm{Cl})$ is the **Sergeev algebra**, which plays an important role in the projective representation theory of the symmetric group.

Example ($A = \mathbb{k}G$, $G = \mathbb{Z}/2\mathbb{Z}$)

$\mathrm{Wr}_n(\mathbb{k}G)$ is the group algebra of the **hyperoctahedral group**, the Weyl group of type B .

Example ($A = \mathbb{k}G$, $G = \mathbb{Z}/r\mathbb{Z}$)

$\mathrm{Wr}_n(\mathbb{k}G)$ is the group algebra of the **complex reflection group** $G(r, 1, n)$.

The wreath product category

Define $\mathcal{W}r(A)$ by adjoining to $\mathcal{S}ym$ morphisms (tokens)

$$\uparrow \begin{array}{c} \bullet \\ a \end{array} : \uparrow \rightarrow \uparrow, \quad a \in A,$$

subject to the relations ($\alpha, \beta \in \mathbb{k}$, $a, b \in A$)

$$\uparrow \begin{array}{c} \bullet \\ 1 \end{array} = \uparrow, \quad \uparrow \begin{array}{c} \bullet \\ \alpha a + \beta b \end{array} = \alpha \uparrow \begin{array}{c} \bullet \\ a \end{array} + \beta \uparrow \begin{array}{c} \bullet \\ b \end{array}, \quad \uparrow \begin{array}{c} \bullet \\ a \\ \bullet \\ b \end{array} = \uparrow \begin{array}{c} \bullet \\ ab \end{array},$$

(so $A \mapsto \text{End}_{\mathcal{W}r(A)}(\uparrow)$, $a \mapsto \uparrow \begin{array}{c} \bullet \\ a \end{array}$ is an algebra homomorphism) and

$$\begin{array}{c} \nearrow \quad \nwarrow \\ \bullet \quad \bullet \\ \searrow \quad \swarrow \end{array} = \begin{array}{c} \nearrow \quad \nwarrow \\ \bullet \\ \searrow \quad \swarrow \end{array} \begin{array}{c} \bullet \\ a \end{array}, \quad a \in A.$$

Then

$$\text{End}_{\mathcal{W}r(A)}(\uparrow^{\otimes n}) = \text{Wr}_n(A).$$

Teleporters

Fix a basis B of A . The **dual basis** is

$$B^\vee = \{b^\vee \mid b \in B\} \quad \text{defined by} \quad \text{tr}(b^\vee c) = \delta_{b,c}, \quad b, c \in B.$$

Exercise 1: $\sum_{b \in B} b \otimes b^\vee \in A \otimes A$ is independent of the basis B .

Exercise 2: For all $a \in A$, we have

$$\sum_{b \in B} ab \otimes b^\vee = \sum_{b \in B} b \otimes b^\vee a, \quad \sum_{b \in B} ba \otimes b^\vee = \sum_{b \in B} b \otimes ab^\vee.$$

Define the **teleporter**

$$\begin{array}{c} \uparrow \quad \uparrow \\ \bullet \text{---} \bullet \\ \uparrow \quad \uparrow \\ \bullet \quad \bullet \end{array} := \sum_{b \in B} \begin{array}{c} \uparrow \\ \bullet \\ \uparrow \end{array} \begin{array}{c} \uparrow \\ \bullet \\ \uparrow \end{array} b^\vee.$$

Then tokens “teleport” across teleporters:

$$\begin{array}{c} \uparrow \quad \uparrow \\ \bullet \text{---} \bullet \\ \uparrow \quad \uparrow \\ \bullet \quad \bullet \end{array} \begin{array}{c} \uparrow \\ \bullet \\ \uparrow \end{array} a = \begin{array}{c} \uparrow \quad \uparrow \\ \bullet \quad \bullet \\ \uparrow \quad \uparrow \\ \bullet \text{---} \bullet \end{array}, \quad \begin{array}{c} \uparrow \quad \uparrow \\ \bullet \text{---} \bullet \\ \uparrow \quad \uparrow \\ \bullet \quad \bullet \end{array} \begin{array}{c} \uparrow \\ \bullet \\ \uparrow \end{array} a = \begin{array}{c} \uparrow \quad \uparrow \\ \bullet \quad \bullet \\ \uparrow \quad \uparrow \\ \bullet \text{---} \bullet \end{array}.$$

Affine wreath product algebras

Define $\mathcal{W}r^{\text{aff}}(A)$ by adjoining to $\mathcal{W}r(A)$ the morphism (**dot**)

$$\uparrow \circlearrowleft : \uparrow \rightarrow \uparrow$$

and relations

$$\begin{array}{c} \nearrow \circlearrowleft \\ \searrow \end{array} - \begin{array}{c} \nearrow \\ \searrow \circlearrowleft \end{array} = \begin{array}{c} \uparrow \\ \text{---} \\ \uparrow \end{array}, \quad \begin{array}{c} \uparrow \\ \text{---} \\ \uparrow \end{array} a = \begin{array}{c} \uparrow \circlearrowleft \\ \text{---} \\ \uparrow \end{array} a, \quad a \in A.$$

We define the **affine wreath product algebra** to be

$$\mathcal{W}r_n^{\text{aff}}(A) := \text{End}_{\mathcal{W}r^{\text{aff}}(A)}(\uparrow^{\otimes n}).$$

Affine wreath product algebras

Example ($A = \mathbb{k}$)

 and $\text{Wr}_n^{\text{aff}}(\mathbb{k})$ is the **degenerate affine Hecke algebra**.

Example ($A = \text{Cl}$, Clifford algebra)

$\text{Wr}_n^{\text{aff}}(\text{Cl})$ is the **affine Sergeev algebra**, aka the **degenerate affine Hecke–Clifford algebra**.

Example ($A = \mathbb{k}G$)

$\text{Wr}_n^{\text{aff}}(\mathbb{k}G)$ is the **wreath Hecke algebra** (Wan–Wang).

Example (Affine zigzag algebras)

When A is a certain zigzag algebra, $\text{Wr}_n^{\text{aff}}(A)$ is related to imaginary strata for quiver Hecke algebras (Kleshchev–Muth).

Hecke algebras

Fix $z \in \mathbb{k}$. Let $\mathcal{H}(z)$ be the strict \mathbb{k} -linear monoidal category with one generating object \uparrow , generating morphisms

$$\begin{array}{c} \nearrow \\ \searrow \end{array}, \begin{array}{c} \nwarrow \\ \searrow \end{array} : \uparrow \otimes \uparrow \rightarrow \uparrow \otimes \uparrow$$

and relations

$$\begin{array}{c} \nearrow \\ \searrow \\ \nearrow \\ \searrow \end{array} = \begin{array}{c} \uparrow \\ \uparrow \end{array}, \begin{array}{c} \nwarrow \\ \searrow \\ \nwarrow \\ \searrow \end{array} = \begin{array}{c} \uparrow \\ \uparrow \end{array}, \begin{array}{c} \nearrow \\ \searrow \\ \nwarrow \\ \searrow \end{array} = \begin{array}{c} \nwarrow \\ \searrow \\ \nearrow \\ \searrow \end{array}, \\ \begin{array}{c} \nearrow \\ \searrow \end{array} - \begin{array}{c} \nwarrow \\ \searrow \end{array} = z \begin{array}{c} \uparrow \\ \uparrow \end{array} \quad (\text{skein relation}).$$

Then

$$H_n(z) := \text{End}_{\mathcal{H}(z)}(\uparrow^{\otimes n})$$

is the **Iwahori–Hecke algebra** of type A_{n-1} (often $z = q - q^{-1}$).

Affine Hecke algebras

Define $\mathcal{H}^{\text{aff}}(z)$ by adjoining to $\mathcal{H}(z)$ the **invertible** morphism

$$\uparrow_{\circ} : \uparrow \rightarrow \uparrow$$

and relations

$$\begin{array}{c} \nearrow \\ \times \\ \searrow \\ \circ \end{array} = \begin{array}{c} \circ \\ \nearrow \\ \times \\ \searrow \end{array}, \quad \begin{array}{c} \nearrow \\ \times \\ \searrow \\ \circ \end{array} = \begin{array}{c} \nearrow \\ \circ \\ \times \\ \searrow \end{array}.$$

Then

$$H_n^{\text{aff}}(z) := \text{End}_{\mathcal{H}^{\text{aff}}}(\uparrow^{\otimes n})$$

is the **affine Hecke algebra** of type A_{n-1} (often $z = q - q^{-1}$).

Frobenius Hecke algebras

Define $\mathcal{H}(A, z)$ by adjoining to $\mathcal{H}(z)$ morphisms

$$\uparrow \bullet a : \uparrow \rightarrow \uparrow, \quad a \in A,$$

subject to the relations ($\alpha, \beta \in \mathbb{k}, a, b \in A$)

$$\uparrow \bullet 1 = \uparrow, \quad \uparrow \bullet \alpha a + \beta b = \alpha \uparrow \bullet a + \beta \uparrow \bullet b, \quad \begin{array}{c} \bullet a \\ \bullet b \end{array} \uparrow = \uparrow \bullet ab,$$

$$\begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} - \begin{array}{c} \nwarrow \nearrow \\ \nearrow \searrow \end{array} = z \begin{array}{c} \uparrow \bullet \\ \uparrow \bullet \end{array},$$

$$\begin{array}{c} \nearrow \searrow \\ \bullet a \nwarrow \nearrow \end{array} = \begin{array}{c} \nearrow \bullet a \\ \nwarrow \searrow \end{array}, \quad \begin{array}{c} \nwarrow \nearrow \\ \bullet a \nearrow \searrow \end{array} = \begin{array}{c} \nwarrow \bullet a \\ \nearrow \searrow \end{array}, \quad \begin{array}{c} \nwarrow \nearrow \\ \nearrow \bullet a \searrow \end{array} = \begin{array}{c} \nwarrow \bullet a \\ \nearrow \searrow \end{array}, \quad \begin{array}{c} \nwarrow \nearrow \\ \nearrow \bullet a \nwarrow \end{array} = \begin{array}{c} \nwarrow \bullet a \\ \nearrow \searrow \end{array}.$$

We call

$$H_n(A, z) := \text{End}_{\mathcal{H}(A, z)}(\uparrow^{\otimes n})$$

a Frobenius Hecke algebra.

Frobenius Hecke algebras

Example ($A = \mathbb{k}$)

$H_n(\mathbb{k}, z)$ is an **Iwahori–Hecke algebra**.

Example ($A = \mathbb{k}G$, G a cyclic group)

$H_n(\mathbb{k}G, z)$ is a **Yokonuma–Hecke algebra**.

Other choices of A yield **new** algebras.

Quantum affine wreath algebras

Define $\mathcal{W}r^{\text{aff}}(A, z)$ by adjoining to $\mathcal{H}(A, z)$ the **invertible** morphism

$$\uparrow_{\circ} : \uparrow \rightarrow \uparrow$$

and relations

$$\begin{array}{c} \nearrow \\ \searrow \\ \circ \end{array} = \begin{array}{c} \circ \\ \nearrow \\ \searrow \end{array}, \quad \begin{array}{c} \nearrow \\ \searrow \\ \circ \end{array} = \begin{array}{c} \nearrow \\ \circ \\ \searrow \end{array}, \quad \begin{array}{c} \uparrow \\ \bullet a \\ \circ \end{array} = \begin{array}{c} \uparrow \\ \circ \\ \bullet a \end{array} .$$

We call

$$\mathcal{W}r_n^{\text{aff}}(A, z) := \text{End}_{\mathcal{W}r^{\text{aff}}(A, z)}(\uparrow^{\otimes n})$$

a **quantum affine wreath algebra**.

One could also call it a **affine Frobenius Hecke algebra**.

Quantum affine wreath algebras

Example ($A = \mathbb{k}$)

$\mathrm{Wr}_n^{\mathrm{aff}}(\mathbb{k}, z)$ is an affine Hecke algebra.

Example ($A = \mathbb{k}G$, G a cyclic group)

$\mathrm{Wr}_n^{\mathrm{aff}}(\mathbb{k}G, z)$ is an affine Yokonuma–Hecke algebra.

Other choices of A yield new algebras.

Example ($A =$ zigzag algebra)

$\mathrm{Wr}_n^{\mathrm{aff}}(A, z)$ is a quantum analogue of affine zigzag algebras.

Jucys–Murphy elements

The Jucys–Murphy elements in $\mathbb{C}S_n$ are

$$J_1 = 0, \quad J_i = (1\ i) + (2\ i) + \cdots + (i-1\ i), \quad i = 2, \dots, n.$$

Useful facts

- J_n commutes with elements of $\mathbb{C}S_{n-1}$.
- the J_i generate a commutative subalgebra of $\mathbb{C}S_n$.
- The basis elements of Young's seminormal representation are eigenvectors for the J_i .

Theorem (Jucys)

The center of $\mathbb{C}S_n$ is generated by symmetric polynomials in the J_i .

Jucys–Murphy elements play a central role in the Okounkov–Vershik approach to the representation theory of symmetric groups.

Jucys–Murphy elements

Recall the **degenerate affine Hecke algebra**:

$$H_n = \mathbb{C}[x_1, \dots, x_n] \otimes \mathbb{C}S_n$$

with relations

$$s_i x_i = x_{i+1} s_i - 1, \quad s_i x_j = x_j s_i, \quad j \neq i, i + 1.$$

Clearly we have an injection

$$\mathbb{C}S_n \hookrightarrow H_n.$$

We also have a surjection

$$H_n \twoheadrightarrow \mathbb{C}S_n, \quad x_i \mapsto J_i.$$

This is an example of a **cyclotomic quotient**. Map is uniquely determined by $x_1 \mapsto 0$. In general, we can quotient by any polynomial in x_1 .

Jucys–Murphy elements

For $1 \leq i < j \leq n$, define

$$t_{i,j} = \begin{array}{cccccccc} \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow \\ & & \bullet & \text{---} & \bullet & & & \\ & & j & & i & & & \end{array}$$

In the **wreath product algebra**, we define the Jucys–Murphy elements

$$J_1 = 0, \quad J_i = t_{1,i}(1\ i) + t_{2,i}(2\ i) + \cdots + t_{i-1,i}(i-1\ i), \quad 1 \leq i \leq n.$$

We have a surjection

$$\mathrm{Wr}_n^{\mathrm{aff}}(A) \twoheadrightarrow \mathrm{Wr}_n(A), \quad x_i \mapsto J_i,$$

where x_i is a dot on the i -th strand.

Quantum version: Can also define Jucys–Murphy elements in $\mathrm{Wr}_n(A, z)$ generalizing usual Jucys–Murphy elements for the Hecke algebra.

Other structure theory results

One can prove many general structure theory results in a uniform way:

- **Demazure operators** (aka divided difference operators)
- **Basis theorem:**

$$\begin{aligned}\mathrm{Wr}_n^{\mathrm{aff}}(A) &\cong A^{\otimes n} \otimes \mathbb{k}[x_1, \dots, x_n] \otimes \mathbb{k}S_n \\ \mathrm{Wr}_n^{\mathrm{aff}}(A, z) &\cong A^{\otimes n} \otimes \mathbb{k}[x_1^{\pm 1}, \dots, x_n^{\pm 1}] \otimes H_n(z)\end{aligned}$$

as \mathbb{k} -modules.

- **Center:**

$$\begin{aligned}Z(\mathrm{Wr}_n^{\mathrm{aff}}(A)) &= (Z(A)^{\otimes n} \otimes \mathbb{k}[x_1, \dots, x_n])^{S_n} \\ Z(\mathrm{Wr}_n^{\mathrm{aff}}(A, z)) &= (Z(A)^{\otimes n} \otimes \mathbb{k}[x_1^{\pm 1}, \dots, x_n^{\pm 1}])^{S_n}\end{aligned}$$

- **Mackey theorem**
- **Cyclotomic quotients** (basis theorem, Mackey theorem, etc.)

Heisenberg categorification

Fix $k \in \mathbb{Z}$. The **Heisenberg category** (Khovanov, Mackaay–S., Brundan) is defined by adjoining to the degenerate affine Hecke category \mathcal{H} an object

\downarrow

and morphisms and relations so that

- \uparrow is right dual to \downarrow ,
- we have an isomorphism

$$\begin{aligned}\uparrow \otimes \downarrow &\cong \downarrow \otimes \uparrow \oplus \mathbb{1}^{\oplus k} && \text{(when } k \geq 0), \\ \uparrow \otimes \downarrow \oplus \mathbb{1}^{\oplus(-k)} &\cong \downarrow \otimes \uparrow && \text{(when } k \leq 0)\end{aligned}$$

(the **inversion relation**).

Acts on modules for degenerate cyclotomic Hecke algebras, categorifies the Heisenberg algebra.

Heisenberg categorification

We can now repeat this with our (quantum) affine wreath categories!

We get:

- quantum Heisenberg category (Licata–S., Brundan–S.–Webster)
- Frobenius Heisenberg category (Rosso–S., S.)
- quantum Frobenius Heisenberg category (Brundan–S.–Webster, work in progress)

These act on modules for the corresponding cyclotomic quotients.

Can also define an odd quantum Frobenius Heisenberg category...
