SUPERCONVERGENCE ANALYSIS OF THE LINEAR FINITE ELEMENT METHOD AND A GRADIENT RECOVERY POSTPROCESSING ON ANISOTROPIC MESHES

WEIMING CAO

ABSTRACT. For the linear finite element method based on general unstructured anisotropic meshes in two dimensions, we establish the superconvergence in energy norm of the finite element solution to the interpolation of the exact solution for elliptic problems. We also prove the superconvergence of the postprocessing process based on the global $L^2$-projection of the gradient of the finite element solution. Our basic assumptions are: (i) the mesh is quasi-uniform under a Riemannian metric and (ii) each adjacent element pair forms an approximate (anisotropic) parallelogram. The analysis follows the same methodology developed by Bank and Xu in 2003 for the case of quasi-uniform meshes, and the results can be considered as an extension of their conclusion to the adaptive anisotropic meshes. Numerical examples involving both internal and boundary layers are presented in support of the theoretical analysis.

1. INTRODUCTION

Recovery type error estimators are widely used in computations based on the finite element method, particularly in various engineering applications, due to their simplicity and robustness. They are often asymptotically exact, i.e., the ratio of the estimated error over the true error tends to 1 as the mesh gets finer and finer. These desirable properties are closely associated with the superconvergence of the finite element solution and its postprocessing. There have been extensive studies on the superconvergence and the recovery type error estimators; see, e.g., monographs by Wahlbin [28], Ainsworth and Oden [1], Babuška and Strouboulis [2], and Zhu [35], for an overview on these topics.

Since the superconvergence is generally resulted from the cancellation of certain lower order terms in the finite element approximation due to local mesh symmetry, its mathematical analysis typically begins with the FE approximations based on uniform meshes, then extends to discretizations on mildly structured meshes [30][31], unstructured quasi-uniform meshes [34][15], and more recently on adaptively refined meshes [29]. For problems exhibiting anisotropic features, e.g., internal and boundary layers, FE solutions based on anisotropic meshes can be much more effective than those based on isotropic ones. Recovery type error estimators have also been applied to this type of computation [12][14][19][25]. Numerical examples demonstrate that these estimators are still robust and reliable at the presence of...
highly anisotropic elements [20, 24]. There have been some theoretical studies on the superconvergence and recovery techniques on structured anisotropic meshes. For instance, Li and Wheeler [16] proved the superconvergence of the FE solution to singular perturbed equations on anisotropic tensor product meshes. Shi, Mao, and Chen [18, 27] published a number of papers on the superconvergence analysis on uniform meshes that stretch anisotropically along coordinate axes. Lin and Lin [17] showed the superconvergence of bilinear elements on anisotropic rectangular meshes. Zhang [32], Xu and Zhang [30] demonstrated that the superconvergence of the FE solution and the asymptotic exactness of their polynomial preserving recovery estimators hold on a class of structured anisotropic meshes. However, we have seen little theoretical work on the case of general adaptively refined unstructured anisotropic meshes.

The purpose of this paper is to provide an analysis of the superconvergence property for the linear finite element approximation of second order problems on adaptively refined anisotropic meshes and an analysis of the recovery type error estimator based on the global $L^2$-projection. More specifically, we consider a class of triangulations that are quasi-uniform under a problem dependent Riemannian metric. By assuming each pair of adjacent elements in the partition forms an approximate parallelogram, we demonstrate that $\|\nabla u_N - \nabla u_I\|$ is superconvergent, where $u_N$ and $u_I$ are the finite element solution and the linear interpolation of the exact solution, respectively, and $N$ is the total number of elements. Furthermore, we prove that $\|\nabla u - P(\nabla u_N)\|$ is superconvergent, where $P$ is the global $L^2$-projection onto the space of continuous piecewise linear functions. These conclusions imply immediately the asymptotic exactness of the recovery based error estimator $\|\nabla u_N - P(\nabla u_N)\|$. This work is an extension of Bank and Xu’s results [3] on the recovery technique based on $L^2$-projection on quasi-uniform meshes.

Needless to say, the convergence and superconvergence of the finite element solution and the error estimator based on its recovery relies intimately on the interplay between the anisotropic behaviors of the PDE solution and the anisotropic features of the meshes. Here we measure the anisotropic behavior of the PDE solution by using some non-negative matrices determined by its higher order directional derivatives introduced in [6, 7, 21, 22]. Then the error bounds can be expressed as a multiple of certain powers of $N$ with the multiplicative constants being some integrals involving the mesh metrics and the anisotropic measures.

A sketch of the paper is as follows: We first extend the concept of approximate parallelograms to the anisotropic meshes. Then we describe the model problem, the anisotropic meshes, and the assumption about the anisotropic behavior of the PDE solutions. We prove the superconvergence of $\|u_N - u_I\|_1$ in Section 4 and the superconvergence of $\|u_N - P(\nabla u_N)\|$ in Section 5. Numerical examples are presented in Section 6. We conclude the paper with some discussions in Section 7.

2. APPROXIMATE PARALLELOGRAMS ON ANISOTROPIC MESHES

Local mesh symmetry plays an essential role in the superconvergence analysis of the finite element approximations. For linear elements, this symmetry typically requires each pair of elements sharing a common edge to form a parallelogram or an approximate parallelogram. We generalize here the concept of $O(h^{1+\alpha})$-approximate parallelogram for quasi-uniform meshes introduced in [8, 15, 26].
First, recall that a parallelogram can be characterized in several ways, e.g., the ratio of opposite side lengths is 1, or the distance between the midpoints of two diagonals is 0, or each pair of opposite sides are in parallel. For a family \{\mathcal{T}_h\} of quasi-uniform triangulations, with \(h\) being the characteristic diameter of elements in \(\mathcal{T}_h\), \(\tau_1 \cup \tau_2\) forms an \(O(h^{1+\alpha})\) approximate parallelogram, if the ratio of its opposite side lengths is of order \(O(h^\alpha)\), or if the distance between the midpoints of two diagonals is \(O(h^{1+\alpha})\), or the angle between the outward normals on each pair of opposite sides are within \(O(h^\alpha)\) range of \(\pi\); see [3,15,26].

Instead of using the above geometric characters to define an approximate parallelogram, we use here the Jacobians of the affine mapping from an equilateral standard element \(\hat{\tau}\) to \(\tau_1\) and \(\tau_2\). Suppose \(\tau_1\) is with vertices \(i,j,k\), and \(\tau_2\) with vertices \(j,i,k\), and \(k\). Let \(J_1\) and \(J_2\) be the Jacobians of the affine mappings from \(\hat{\tau}\) to \(\tau_1\) and \(\tau_2\) with vertices \(k\) and \(k\) being the images of the same vertex on \(\hat{\tau}\), respectively. Then \(\tau_1 \cup \tau_2\) forms a parallelogram iff \(J_1 = -J_2\), and \(\tau_1 \cup \tau_2\) forms an \(O(h^{1+\alpha})\) approximate parallelogram, iff
\[
\|I + J_1^{-1} J_2\| \simeq \|I + J_1 J_2^{-1}\| = O(h^\alpha).
\]
In addition, \(\{\mathcal{T}_h\}\) is a regular family of partition iff \(\text{cond}(\mathcal{T}_\tau) = O(1)\) for all \(\tau \in \mathcal{T}_h\).

For discretization involving anisotropic meshes, the element diameter is not a proper parameter for describing the asymptotic behaviors, since an element can have much different length scales in different directions. Instead, the total number \(N\) of elements is essential. Thus we introduce the following concept of the \(O(N^{-(1+\alpha)/2})\)-approximate parallelogram.

**Definition 2.1.** Let \(\tau_1\) and \(\tau_2\) be a pair of elements sharing a common edge, and let \(J_1\) and \(J_2\) be the Jacobians of the affine mappings from equilateral standard element \(\hat{\tau}\) to \(\tau_1\) and \(\tau_2\). \(\tau_1 \cup \tau_2\) is called forming an \(O(N^{-(1+\alpha)/2})\)-approximate parallelogram, if
\[
\|I + J_1^{-1} J_2\| = O(N^{-\alpha/2}).
\]
When \(\{\mathcal{T}_h\}\) is quasi-uniform, we have \(h = \text{diam}(\tau) = O(N^{-1/2})\), and the above definition is reduced to the \(O(h^{1+\alpha})\)-approximate parallelogram for shape regular elements described in [3,15].

It should be noted that this definition is independent of the ordering of \(\tau_1\) and \(\tau_2\). It is easy to see that condition (1) is equivalent to
\[
\|I + J_2^{-1} J_1\| = O(N^{-\alpha/2}).
\]
Indeed, we have from (1) that
\[
\|J_2^{-1} J_1\| = \|(I - (I + J_1^{-1} J_2))^{-1}\| \leq \frac{1}{1 - \|I + J_1^{-1} J_2\|} = O(1)
\]
Hence
\[
\|I + J_2^{-1} J_1\| = \|J_2^{-1} J_1 (I + J_1^{-1} J_2)\| \leq \|J_2^{-1} J_1\| \cdot \|I + J_1^{-1} J_2\| = O(N^{-\alpha/2}).
\]
However, this definition is not equivalent to requiring that
\[
\|I + J_1 J_2^{-1}\| = O(N^{-\alpha/2}).
\]
We give here two examples of the anisotropic element pairs, one forms an approximate parallelogram by satisfying (1), and another does not, even though it satisfies (2). We choose condition (1) over (2) since the former measures the deviation...
of $\tau_1 \cup \tau_2$ from an exact parallelogram in the coordinate system for the standard element, which is fixed for all elements and all mesh sizes.

![Diagram](image)

**Figure 1.** Left: a pair of elements that forms an approximate parallelogram; Right: a pair of elements that does not form an approximate parallelogram.

**Example 1.** Let $\epsilon = N^{-\alpha/2} \to 0$, and let the standard element be the equilateral triangle with vertices $(\cos \theta_m, \sin \theta_m)$, $\theta_m = \frac{\pi}{3} + \frac{2m}{3} \pi$, $m = 0, 1, 2$. Choose $x_1 = (0, 0)$, $x_2 = (1 - \epsilon, 0)$, $x_3 = (1, \epsilon)$, and $x_4 = (0, \epsilon)$. Elements $\tau_1 = \Delta x_1 x_3 x_4$, and $\tau_2 = \Delta x_2 x_3 x_1$; see Figure 1(a). The center of $\tau_1$ is $x_c = (\frac{1}{3}, \frac{2\epsilon}{3})$. Then the affine mapping from $\hat{\tau}$ to $\tau_1$ (with $(0, 1)$ to $x_4$) is

$$x = J_1 \xi + x_c$$

with the Jacobian $J_1$ for the mapping being

$$J_1 = \left( \begin{array}{c} \frac{1}{\sqrt{3}} (x_3 - x_1), x_4 - x_c \end{array} \right) = \left( \begin{array}{c} \frac{1}{\sqrt{3}} \frac{1}{3} \frac{1}{3} \\ \frac{1}{\sqrt{3}} \frac{1}{3} \frac{1}{3} \end{array} \right).$$

Similarly, the Jacobian for the affine mapping from $\hat{\tau}$ to $\tau_2$ (with $(0, 1)$ to $x_2$) is

$$J_2 = \left( \begin{array}{c} -\frac{1}{\sqrt{3}} \frac{1}{3} \frac{1}{3} \\ -\frac{1}{\sqrt{3}} \frac{1}{3} \frac{1}{3} \end{array} \right) = -J_1 + \left( \begin{array}{c} 0 \ -\frac{2\epsilon}{3} \\ 0 \ 0 \end{array} \right).$$

It is elementary to verify that

$$I + J_1^{-1}J_2 = J_1^{-1} \cdot \left( \begin{array}{c} 0 \ -\frac{2\epsilon}{3} \\ 0 \ 0 \end{array} \right) = \left( \begin{array}{c} 0 \ -\frac{\epsilon}{\sqrt{3}} \\ 0 \ 0 \end{array} \right),$$

and that

$$I + J_2J_1^{-1} = \left( \begin{array}{c} 0 \ -\frac{2\epsilon}{3} \\ 0 \ 0 \end{array} \right) \cdot J_1^{-1} = \left( \begin{array}{c} \epsilon \ -1 \\ 0 \ 0 \end{array} \right).$$

Thus (1) holds for $\tau_1 \cup \tau_2$, and it forms an $O(N^{-(1+\alpha)/2})$-approximate parallelogram, even though the left and right sides always form a $45^\circ$ angle, and their lengths differ by a constant multiple $\sqrt{2}$. Note that (3) is not satisfied in this case.

**Example 2.** Let $x_1 = (-1, 0)$, $x_2 = (0, -\epsilon)$, $x_3 = (1, 0)$, and $x_4 = (0, 2\epsilon)$. Elements $\tau_1 = \Delta x_1 x_2 x_4$, and $\tau_2 = \Delta x_3 x_4 x_2$; see Figure 1(b). The Jacobians for the mapping from $\hat{\tau}$ to $\tau_1$ and $\tau_2$ with $(1, 0)$ to $x_1$ and $x_3$, respectively, are

$$J_1 = \left( \begin{array}{c} 0 \ -\frac{2\epsilon}{3} \\ \sqrt{3} \ -\frac{\epsilon}{3} \end{array} \right), \quad J_2 = \left( \begin{array}{c} 0 \ \frac{2\epsilon}{3} \\ -\sqrt{3} \ -\frac{\epsilon}{3} \end{array} \right) = -J_1 + \left( \begin{array}{c} 0 \ 0 \\ 0 \ -\frac{2\epsilon}{3} \end{array} \right).$$

Clearly,

$$I + J_1^{-1}J_2 = \left( \begin{array}{c} 0 \ -\frac{2\epsilon}{3} \\ 0 \ 0 \end{array} \right),$$

$$I + J_2J_1^{-1} = \left( \begin{array}{c} 0 \ -\frac{2\epsilon}{3} \\ 0 \ 0 \end{array} \right) \cdot J_1^{-1} = \left( \begin{array}{c} \epsilon \ -1 \\ 0 \ 0 \end{array} \right).$$
and

\[ I + J_2 J_1^{-1} = \begin{pmatrix} 0 & 0 \\ \epsilon & 0 \end{pmatrix}. \]

Thus (1) does not hold for \( \tau_1 \cup \tau_2 \), and it does not form an \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram. Nevertheless, (3) is satisfied.

To further elaborate the geometric meaning of the approximate parallelograms, we list in the following several lemmas.

**Lemma 2.1.** If \( \tau_1 \cup \tau_2 \) forms an \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram, then

\[ \frac{|\tau_2|}{|\tau_1|} = 1 + O(N^{-\alpha/2}). \]

This conclusion comes from the fact that (1) implies

\[ \frac{|\tau_2|}{|\tau_1|} = \det(J_1^{-1} J_2) = \det(-I + (I + J_1^{-1} J_2)) = 1 + O(N^{-\alpha/2}). \]

**Lemma 2.2.** A pair of adjacent elements \( \tau_1 \) and \( \tau_2 \) forms an \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram, if and only if there exists an affine mapping \( F \) such that \( F(\tau_1) \cup F(\tau_2) \) forms a shape regular \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram.

**Proof.** Note that the Jacobians for the affine mapping from \( \hat{\tau} \) to \( F(\tau_1) \) and \( F(\tau_2) \) are

\[ \hat{J}_1 = FJ_1 \text{ and } \hat{J}_2 = FJ_2, \]

resp. If \( F(\tau_1) \cup F(\tau_2) \) forms a shape regular \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram, then

\[ \|I + \hat{J}_1^{-1} \hat{J}_2\| = O(N^{-\alpha/2}), \]

which implies (1), and thus \( \tau_1 \cup \tau_2 \) forms an \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram.

On the other hand, if \( \tau_1 \cup \tau_2 \) forms an \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram, choose \( F = J_1^{-1} \). Then \( F(\tau_1) \) is equilateral. \( F(\tau_2) \) is shape regular since (1) implies

\[ \text{cond}(FJ_2) \leq C. \]

Furthermore,

\[ \|I + \hat{J}_1^{-1} \hat{J}_2\| = \|I + J_1^{-1} J_2\| = O(N^{-\alpha/2}). \]

Thus \( F(\tau_1) \cup F(\tau_2) \) forms a shape regular \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram.

The above lemma indicates that an anisotropic \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram has to be the affine image of a shape regular \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram. Note that for a pair of shape regular elements, if they form an \( O(h^{1+\alpha}) \)-approximate parallelogram, then another element pair obtained by swapping the diagonals of this approximate parallelogram also forms an \( O(h^{1+\alpha}) \)-approximate parallelogram. Namely, edge swapping in a mesh does not affect whether two adjacent elements form an approximate parallelogram or not. This prompts us to introduce yet another equivalent condition for approximate parallelogram by using only the location of four vertices of the adjacent elements.

**Lemma 2.3.** Let \( Q = \tau_1 \cup \tau_2 \), and let \( \hat{Q} \) be the standard quadrilateral element, e.g., \([0,1]^2\). \( J_Q \) is the Jacobian of the bilinear mapping from \( \hat{Q} \) to \( Q \), and \( d \) is the vector connecting two midpoints of the diagonals of \( Q \). Then \( \tau_1 \cup \tau_2 \) forms an \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram, iff

\[ |J_Q^{-1}(\xi)d| = O(N^{-\alpha/2}), \quad \forall \xi \in \hat{Q}. \]
Proof. First we note that both conditions (I) and (II) are invariant under any affine transform of \( \tau_1 \cup \tau_2 \). Thus we only have to show the above lemma in the cases \( \tau_1 \) and \( \tau_2 \) are shape regular. In particular, we may assume, without loss of generality, that \( Q \) is with vertices \( x_1 = (0,0), x_2 = (1,0), x_3 = (1+\delta_1, 1+\delta_2), \) and \( x_4 = (0,1) \). It is ready to verify that \( d = \frac{1}{2}(x_1 + x_3 - x_2 - x_4) = \frac{1}{2}[\delta_1, \delta_2]^T \) and that the bilinear mapping \( x = B(\xi) \) from \( Q \) to \( Q \) is
\[
B(\xi) = x_1 + \xi_1(x_2 - x_1) + \xi_2(x_4 - x_1) + 2\xi_1\xi_2 d
\]
and
\[
J_Q(\xi) = \frac{\partial x}{\partial \xi} = \begin{bmatrix} 1 + \delta_1 \xi_2 & \delta_1 \xi_1 \\ \delta_2 \xi_2 & 1 + \delta_2 \xi_1 \end{bmatrix}.
\]
An elementary calculation leads to
\[
J_Q^{-1}(\xi)d = \frac{1}{2(1 + \delta_1 \xi_2 + \delta_2 \xi_1)} \begin{bmatrix} \delta_1 \\ \delta_2 \end{bmatrix}.
\]
Since for all \( \xi \in [0,1]^2 \), we have
\[
1 - \sqrt{2}|d| \leq 1 + \delta_1 \xi_2 + \delta_2 \xi_1 \leq 1 + \sqrt{2}|d|.
\]
Thus (III) is satisfied iff \( |d| = O(N^{-\alpha/2}) \), i.e., \( \tau_1 \cup \tau_2 \) forms an \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram. The above lemma indicates that (III) is also a sufficient condition and can be used even in the case of anisotropic meshes.

3. Model problems and their FE approximation

We consider the following homogeneous Dirichlet problem of a second order elliptic equation:
\[
\begin{cases}
-\nabla \cdot (A \nabla u + b \ u) + d \ u = f, & \text{in } \Omega, \\
u|_{\partial \Omega} = 0.
\end{cases}
\]
We assume in this paper \( A \) is a positive definite constant matrix, \( b, d \) are suitably smooth functions and equation (6) is strongly elliptic.

**FE approximation:** Let \( \{\mathcal{T}_N\} \) be a family of regular partitions of \( \Omega \) \[3\]. Here, \( N \) represents the total number of elements in \( \mathcal{T}_N \). Define \( S_N \) be the space of continuous piecewise linear functions based on partition \( \mathcal{T}_N \). \( V_N = S_N \cap H^1_0(\Omega) \). Then the finite element method for solving (II) is to find the approximate solution \( u_N \in V_N \) such that
\[
a(u_N, v_N) = (f, v_N), \quad \forall v_N \in V_N,
\]
where bilinear form \( a(\cdot, \cdot) \) is defined as
\[
a(u, v) = (A \nabla u, \nabla v) + (u, b \cdot \nabla v) + (du, v).
\]

**Anisotropic meshes:** Since the convergence and superconvergence of the finite element solution depend closely on the properties of meshes, we restrict our analysis on a class of anisotropic meshes that are quasi-uniform under a given metric.
precisely, let \( M \) be a continuous Riemannian metric on \( \bar{\Omega} \). For each element \( \tau \in \mathcal{T}_N \), let \( M_{\tau} \) be the average of \( M \) over \( \tau \), and its eigen-decomposition is of the form

\[
M_{\tau} = T_{\tau} \cdot \Lambda_{\tau} \cdot T_{\tau}^T,
\]

where \( \Lambda_{\tau} \) is diagonal and \( T_{\tau} \) is orthonormal. Define

\[
F_{\tau} = T_{\tau} \Lambda_{\tau}^{-\frac{1}{2}}.
\]

A family of triangulations \( \{ \mathcal{T}_N \} \) is called quasi-uniform under metric \( M \), if for all \( \tau \in \mathcal{T}_N \), \( \tilde{\tau} = F_{\tau}^{-1} \tau \) are shape regular and of about the same size; see [6–8]. Let \( J_{\tau} \) be the Jacobian of the affine mapping from standard element \( \tilde{\tau} \) to element \( \tau \). Then \( \{ \mathcal{T}_N \} \) is quasi-uniform under metric \( M \) if and only if

\[
\|F_{\tau}^{-1}J_{\tau}\| \simeq (\|J_{\tau}^{-1}F_{\tau}\|)^{-1} \simeq (C_M/N)^{1/2}, \quad \forall \tau \in \mathcal{T}_N,
\]

where

\[
C_M = \int_{\Omega} |\det(M)|^{1/2}.
\]

Clearly, the error for the finite element approximation depends on the interplay between the anisotropic features of the meshes and the anisotropic behavior of the solutions. In order to derive the convergence and superconvergence for the linear finite element approximation, we need the following assumption to characterize the anisotropic behavior of the second and third derivatives of solution \( u \).

**Assumption on \( D^2u \) and \( D^3u \):** Let \( Q_2(x) \) and \( Q_3(x) \) be \( 2 \times 2 \) symmetric non-negative definite matrices. For \( m = 2, 3 \), we assume at each \( x \in \Omega \) that

\[
|(s \cdot \nabla)^m u(x)| \leq (s \cdot Q_m(x)s)^{m/2}, \quad \forall s \in \mathbb{R}^2.
\]

Such matrices always exist as long as \( D^2u \) and \( D^3u \) exist. For instance, \( Q_2(x) \) can be chosen as \( |\nabla^2u| I \), where \( I \) is the identity matrix and \( |\nabla^2u| = \max_{\|s\|=1} \|s \cdot \nabla^2u\| \). It can also be chosen as \( \text{abs}(\nabla^2u(x)) \), which is the matrix of the same eigenvectors as \( \nabla^2u(x) \) but with the eigenvalues equal to the absolute values of \( \nabla^2u(x) \)'s. Note that the left-hand side of (12) is the directional derivative along \( s \), the “smaller” the matrix \( Q_m \), the more precise it describes the anisotropic behaviors of \( D^m u \). A geometric explanation of (12) and a numerical procedure to find these matrices can be found in [3–7]. More recently, Mirebeau studied systematically how to find these matrices and applied them in anisotropic mesh generation. He also derived an explicit formula to define \( Q_3 \); see [21,22] for details.

The effects of the anisotropic mesh for approximating a solution of anisotropic derivatives can be appreciated by the following inequalities. Let \( \tilde{u} \) be the pull-back of \( u|_{\tau} \) under the affine mapping from the standard element \( \tilde{\tau} \) to element \( \tau \). Then we have \( \tilde{\nabla} = J_{\tau}^T \nabla \), and

\[
|(s \cdot \tilde{\nabla})^m \tilde{u}| \leq (s \cdot J_{\tau}^T Q_m J_{\tau} s)^{m/2}, \quad \forall s \in \mathbb{R}^2
\]

which implies

\[
|\tilde{D}^m \tilde{u}| \leq \|J_{\tau}^T Q_m J_{\tau}\|^{m/2}.
\]

When \( D^m u \) is highly anisotropic, the eigenvalues of \( Q_m \) are of very different magnitudes. A proper choice of \( J_{\tau} \) may make \( |\tilde{D}^m \tilde{u}| \) significantly smaller than \( |D^m u| \).

**a-priori error estimate:** By the ellipticity of equation (4), it follows from the interpolation error estimates (see Theorem 2.1 in [7]) the following a priori error estimate for the linear finite element approximation of (4).
Theorem 3.1. Suppose \( \{T_N\} \) is quasi-uniform under metric \( M \), and \( u_N \) is the linear finite element approximation of the solution \( u \) of (9). Furthermore, assume the second derivative \( D^2u \) satisfies assumption (12) about its anisotropic behavior. Then there exists a constant \( c \) independent of \( u \) and \( N \) such that

\[
\|u - u_N\|_{1,\Omega} \leq cN^{-1/2} \cdot \left\{ C_M \int \|F^{-1}\|_2^2 \left\| F^T Q_2 F \right\|_2 \right\}^{1/2},
\]

where \( F \) and \( C_M \) are determined by \( M \) as in (9) and (11).

Remark 3.1. When \( \nabla^2 u \) is positive definite on \( \Omega \), we may choose \( Q_2 = \nabla^2 u \) in (12), and choose \( M = c(\lambda_{max}/\lambda_{min})^{1/4} \cdot \nabla^2 u \), where \( \lambda_{max} \) and \( \lambda_{min} \) are the largest and smallest eigenvalues of \( \nabla^2 u \), respectively; see [5] [7]. In this case, (15) is reduced to

\[
\|u - u_N\|_{1,\Omega} \leq cN^{-1/2} \|\lambda_{min}\lambda_{max}^{3/4}\|_{L^1(\Omega)}.
\]

In contrast, if we allow only shape regular elements, then the best isotropic mesh metric to minimize the error bound in (15) would be \( M = \lambda_{max}I \), and the error bound for \( \|u - u_N\|_{1,\Omega} \) would be \( cN^{-1/2}\|\lambda_{max}\|_{L^1(\Omega)} \), which is clearly much larger than for the anisotropic case when \( \lambda_{max} \) and \( \lambda_{min} \) are of much different magnitudes.

4. Superconvergence of FE solution

First we recall a basic lemma developed by Bank and Xu [3] for analyzing the “weak convergence” of linear interpolation on a triangular element. Let \( \tau \) be an element with vertices \( x_k \), \( k = 1, 2, 3 \). Denote by \( \theta_k \) the internal angle of \( \tau \) at \( x_k \). Let \( \ell_k = x_{k-1} - x_{k+1} \) be the edge (directed counterclockwise) opposite to \( x_k \), and \( \ell_k = |\ell_k| \) is its length. \( t_k = \ell_k/\ell_k \) and \( n_k \) are the unit tangential and outward normal directions on \( \ell_k \), respectively, and

\[
\xi_k = -n_{k+1} \cdot An_{k-1}.
\]

Furthermore, let \( \phi_k \) be the nodal basis function associated with \( x_k \), \( q_k = \phi_{k+1}\phi_{k-1} \), and \( \psi_k = \phi_k(1 - \phi_k) \).

Lemma 4.1. Let \( \tau \) be an element in \( T_N \), and let \( u \) be the linear interpolation of \( u \) at the vertices of \( \tau \). Then

\[
\int_{\tau} \nabla(u - u_\tau) \cdot A \nabla u_\tau = \sum_{k=1}^{3} \int_{\ell_k} \frac{\xi_k q_k}{2\sin \theta_k} \cdot \left\{ (\ell_{k+1}^2 - \ell_{k-1}^2) \frac{\partial^2 u}{\partial t_k^2} + 4|\tau| \frac{\partial^2 u}{\partial t_k \partial n_k} \right\}
\]

\[
\cdot \frac{\partial u_\tau}{\partial t_k} - \sum_{k=1}^{3} \frac{\xi_k \ell_k}{2\sin^2 \theta_k} \left\{ \ell_{k+1}\psi_{k-1} \frac{\partial^3 u}{\partial t_{k+1}\partial t_{k-1}} + \ell_{k-1}\psi_{k+1} \frac{\partial^3 u}{\partial t_{k-1}\partial t_{k+1}} \right\}.
\]

This lemma plays a fundamental role in the superconvergence analysis [3] [30]. It separates not only the error contribution from each edge of the elements, but more importantly, the contributions from normal and tangential derivatives. It makes the cancellation of lower order error terms much easier. Moreover, (16) is an identity valid on any triangle. We shall use it on the standard element \( \hat{\tau} \).

Theorem 4.1. Let \( u_\tau \) and \( u_N \) be the linear interpolation and the finite element approximation of \( u \), respectively. Suppose \( D^2u \) and \( D^3u \) satisfy assumption (12),
and each pair of adjacent elements in $T_N$ forms an $O(N^{-(1+\alpha)/2})$-approximate parallelogram. Then

\begin{equation}
\|u_N - u_I\|_{1, \Omega} \leq c \left\{ \sum_{\tau} \int_{\Omega} (1 + N^{-\alpha} \|J_{\tau}^{-1}\|_4 \|J_{\tau}\|^2) \cdot \|J_{\tau}^T Q_2 J_{\tau}\|^2 + \|J_{\tau}^{-1}\|_4 \|J_{\tau}\|^2 \cdot \|J_{\tau}^T Q_3 J_{\tau}\|^3 \right\}^{1/2}.
\end{equation}

In addition, if the partition $T_N$ is quasi-uniform under metric $M$, then we have

\begin{equation}
\|u_N - u_I\|_{1, \Omega} \leq c N^{-1/2} \left\{ \int_{\Omega} (\langle M \rangle ^2 N^{-1} + C_M N^{-\alpha} \|F\|_4^2 \|F\|_4^2) \cdot \|F^T Q_2 F\|^2 + (C_M)^2 N^{-1} \|F\|_4^2 \cdot \|F^T Q_3 F\|^3 \right\}^{1/2},
\end{equation}

where $F$ and $C_M$ are determined by $M$ as in (9) and (11).

Proof. By the ellipticity of $a(\cdot, \cdot)$ and the orthogonality of the finite element approximation,

\begin{equation}
\|u_N - u_I\|_{1, \Omega} \leq c \sup_{v_N} \frac{\|a(u_N - u_I, v_N)\|}{\|v_N\|_{1, \Omega}} = c \sup_{v_N} \frac{\|a(u - u_I, v_N)\|}{\|v_N\|_{1, \Omega}}.
\end{equation}

To prove the theorem, we only have to bound $a(u - u_I, v_N)$ by a certain multiple of $\|v_N\|_1$ for arbitrary $v_N \in S_N$. Note that

\begin{equation}
a(u - u_I, v_N) = \sum_{\tau} \int_{\tau} \nabla (u - u_I) \cdot A \nabla v_N + \int_{\Omega} (u - u_I) (b \cdot \nabla v_N + dv_N).
\end{equation}

First we estimate the second term on the right-hand side of the above equation. On each element $\tau \in T_N$, let $F_\tau$ be the affine mapping from the equilateral standard element $\hat{\tau}$ to $\tau$, $\hat{u}_\tau = u \circ F_\tau$, and let $\hat{u}_I = \bar{\Pi}_1 \hat{u}_\tau$ be the linear interpolation of $\hat{u}_\tau$ on $\hat{\tau}$. It follows from assumption (12) on the anisotropic behavior of $D^2 u$ that

\begin{align*}
|\int_{\Omega} (u - u_I) \cdot (b \cdot \nabla v_N + dv_N) | &\leq c \|u - u_I\| \|v_N\|_1 \\
&\leq c \|v_N\|_1 \left\{ \sum_{\tau} \int_{\tau} \|u - u_I\|_1^2 \right\}^{1/2} \\
&\leq c \|v_N\|_1 \left\{ \sum_{\tau} |\tau| \cdot \int_{\hat{\tau}} \|\hat{u} - \hat{u}_I\|_1^2 \right\}^{1/2} \\
&\leq c \|v_N\|_1 \left\{ \sum_{\tau} |\tau| \cdot \int_{\hat{\tau}} \|\hat{D}^2 \hat{u}\|_1^2 \right\}^{1/2} \\
&\leq c \|v_N\|_1 \left\{ \sum_{\tau} \int_{\tau} \|J_{\tau}^T Q_2 J_{\tau}\|_2^2 \right\}^{1/2}.
\end{align*}

Now we deal with the first term on the right-hand side of (19). On each element $\tau$, let $J_{\tau}$ be the Jacobian of the mapping $F_{\tau}$. Let $\hat{A}_\tau = J_{\tau}^{-1} A J_{\tau}^T$ and $\hat{\xi}_k = -\hat{\eta}_{k+1} \cdot A \hat{n}_{k-1}$. Then by a change of variables, we have $\hat{\nabla} = J_{\tau}^T \nabla$ and

\begin{equation}
\sum_{\tau \in T_N} \int_{\tau} \nabla (u - u_I) \cdot A \nabla v_N = \sum_{\tau \in T_N} |\tau| \cdot \int_{\hat{\tau}} \hat{\nabla} (\hat{u}_\tau - \hat{u}_I) \cdot \hat{A}_\tau \hat{\nabla} \hat{v}_N.
\end{equation}
Applying Lemma 4.1 to the integrals on \( \hat{\tau} \) for each \( \tau \), and noting that \( |\hat{\tau}| = \frac{3\sqrt{3}}{4} \), \( |\hat{\ell}_k| = \sqrt{3} \) and \( \theta_k = \frac{\pi}{3} \) for all \( k = 1, 2, 3 \), we have

\[
(21) \quad \int_{\hat{\tau}} \nabla (\hat{u}_\tau - \hat{u}_J) \cdot \hat{A}_\tau \hat{\nabla} v_N = \sum_{k=1}^{3} \int_{\hat{\ell}_k} \xi_k q_k \cdot \frac{\partial^2 \hat{u}_\tau}{\partial t_k \partial n_k} \cdot \frac{\partial \hat{v}_N}{\partial t_k} - 2 \sum_{k=1}^{3} \int_{\hat{\tau}} \xi_k (\psi_{k+1} \frac{\partial^3 \hat{u}_\tau}{\partial^2 t_{k+1} \partial t_k} + \psi_{k-1} \frac{\partial^3 \hat{u}_\tau}{\partial^2 t_{k-1} \partial t_{k+1}}) \cdot \frac{\partial \hat{v}_N}{\partial t_k}.
\]

Summing up the above integrals for all \( \tau \in T_N \) and grouping together the two line integrals associated with a common edge \( e = \tau \cap \tau' \), we have

\[
\sum_{\tau \in T_N} \int_{\tau} \nabla (u - u_\tau) \cdot A \nabla v_N = I_1 + I_2,
\]

where

\[
I_1 = \sum_{\tau \in T_N} |\tau| \sum_{k=1}^{3} \int_{\hat{\ell}_k} \xi_k q_k \cdot \frac{\partial^2 \hat{u}_\tau}{\partial t_k \partial n_k} \cdot \frac{\partial \hat{v}_N}{\partial t_k} = \sum_{e = \tau \cap \tau'} \left( \int_{\hat{\ell}} |\tau| q \xi_{\tau} \frac{\partial^2 \hat{u}_\tau}{\partial t \partial n} \cdot \frac{\partial \hat{v}_N}{\partial t} + \int_{\hat{\ell}'} |\tau'| q \xi_{\tau'} \frac{\partial^2 \hat{u}_\tau}{\partial t \partial n} \cdot \frac{\partial \hat{v}_N}{\partial t} \right),
\]

\[
I_2 = -2 \sum_{\tau \in T_N} \left( |\tau| \sum_{k=1}^{3} \int_{\hat{\tau}} \xi_k (\psi_{k+1} \frac{\partial^3 \hat{u}_\tau}{\partial^2 t_{k+1} \partial t_k} + \psi_{k-1} \frac{\partial^3 \hat{u}_\tau}{\partial^2 t_{k-1} \partial t_{k+1}}) \cdot \frac{\partial \hat{v}_N}{\partial t_k} \right).
\]

We first bound the integrals in \( I_2 \). Note that \( |\psi_k| \leq \frac{1}{4}, |q_k| \leq 1, \)

\[
|\xi_k| \leq \|A_\tau\| \leq \|J^{-1}_\tau\| \|A\|
\]

and

\[
\left| \frac{\partial \hat{v}_N}{\partial t_k} \right| \leq \|\nabla \hat{v}_N\| \leq \|J\| \|\nabla v_N\|,
\]

Furthermore, by assumption (12), we have

\[
\left| \frac{\partial^3 \hat{u}_\tau}{\partial^2 t_{k+1} \partial t_k} \right| \leq \|\hat{D}^3 \hat{u}_\tau\| \leq \|J^2_\tau Q_3 J_\tau\|^{3/2}.
\]

Thus

\[
|I_2| \leq c \sum_{\tau \in T_N} \int_{\tau} \|J^{-1}_\tau\| \|J_\tau\| \|J^2_\tau Q_3 J_\tau\|^{3/2} \|\nabla v_N\|
\]

\[
\leq c \left( \sum_{\tau \in T_N} \int_{\tau} \|J^{-1}_\tau\|^4 \|J_\tau\|^2 \|J^2_\tau Q_3 J_\tau\|^3 \right)^{1/2} \|\nabla v_N\|_{L^2(\Omega)}.
\]

Next, we deal with \( I_1 \). Note that for each term in the sum up to \( I_1 \) we may assume \( \hat{e} = \hat{e}' \), i.e., the common edge \( e \) of \( \tau \) and \( \tau' \) is the images of the same edge in the equilateral standard element under \( F_\tau \) and \( F_{\tau'} \). Otherwise, a rotation of the standard element by angle \( \pm 120^\circ \) for one of the integrals will convert it to such a case. With this in mind, we have

\[
\frac{\partial \hat{v}_N|_{\tau}}{\partial t} = - \frac{\partial \hat{v}_N|_{\tau'}}{\partial t}.
\]
and
\[
I_1 = \sum_{e = \tau \cap \tau'} \int_{\hat{e}} \left( |\tau| \dot{\xi}_r \frac{\partial^2 \hat{u}_r}{\partial t \partial \hat{n}} + |\tau'| \dot{\xi}_{r'} \frac{\partial^2 \hat{u}_{r'}}{\partial t \partial \hat{n}} \right) \cdot q \cdot \frac{\partial \hat{v}_N}{\partial \hat{t}}.
\]

We split the integrand into
\[
|\tau| \dot{\xi}_r \frac{\partial^2 \hat{u}_r}{\partial t \partial \hat{n}} + |\tau'| \dot{\xi}_{r'} \frac{\partial^2 \hat{u}_{r'}}{\partial t \partial \hat{n}} = |\tau| (\dot{\xi}_r - \dot{\xi}_{r'}) \frac{\partial^2 \hat{u}_r}{\partial t \partial \hat{n}}
\]

On the other hand,
\[
\frac{\partial^2 \hat{u}_r}{\partial t \partial \hat{n}}\bigg|_{\hat{e}} = (\hat{\mathbf{i}} \cdot \hat{\nabla})(\hat{\mathbf{n}} \cdot \hat{\nabla}) \hat{u}_r = (J_r \hat{\mathbf{i}} \cdot \nabla)(J_r \hat{\mathbf{n}} \cdot \nabla) u
\]

and
\[
\frac{\partial^2 \hat{u}_{r'}}{\partial t \partial \hat{n}}\bigg|_{\hat{e}} = (\hat{\mathbf{i}} \cdot \hat{\nabla})(\hat{\mathbf{n}} \cdot \hat{\nabla}) \hat{u}_{r'} = (J_{r'} \hat{\mathbf{i}} \cdot \nabla)(J_{r'} \hat{\mathbf{n}} \cdot \nabla) u.
\]

By the fact that \( J_r \hat{\mathbf{i}} = -J_{r'} \hat{\mathbf{i}} \), we have
\[
\frac{\partial^2 \hat{u}_r}{\partial t \partial \hat{n}} - \frac{\partial^2 \hat{u}_{r'}}{\partial t \partial \hat{n}} = |\tau| (\dot{\xi}_r - \dot{\xi}_{r'}) \frac{\partial^2 \hat{u}_r}{\partial t \partial \hat{n}} - \frac{\partial^2 \hat{u}_{r'}}{\partial t \partial \hat{n}}.
\]

It follows from the assumption that \( \tau \cup \tau' \) forms an \( O(N^{-(1+\alpha)/2}) \)-approximate parallelogram such that
\[
|\dot{\xi}_r - \dot{\xi}_{r'}| = |\hat{n}_{k+1} \cdot (\hat{A}_r - \hat{A}_{r'}) \hat{n}_{k-1}|
\]

On the other hand,
\[
\frac{\partial^2 \hat{u}_r}{\partial t \partial \hat{n}} = (\hat{\mathbf{i}} \cdot \hat{\nabla})(\hat{\mathbf{n}} \cdot \hat{\nabla}) \hat{u}_r = (J_r \hat{\mathbf{i}} \cdot \nabla)(J_r \hat{\mathbf{n}} \cdot \nabla) u
\]

Put the above two bounds and the bound from Lemma 2.1 into (22), we have
\[
|I_1| \leq cN^{-\alpha/2} \sum_{e = \tau \cap \tau'} |\tau| \cdot \|J_{r'}^{-1}\|^2 \cdot |\nabla v_N| \cdot \int_{\hat{e}} |\hat{D}^2 \hat{u}_r|
\]
\[
\leq cN^{-\alpha/2} \sum_{\tau \in T_N} |\tau| \cdot \|J_{r'}^{-1}\|^2 \cdot \|J_r\| \cdot |\nabla v_N| \cdot \left\{ \int_{\hat{\tau}} \left( |\hat{D}^2 \hat{u}_r|^2 + |\hat{D}^3 \hat{u}_r|^2 \right) \right\}^{1/2}
\]
\[
\leq cN^{-\alpha/2} \sum_{\tau \in T_N} |\tau|^{1/2} \cdot \|J_{r'}^{-1}\|^2 \cdot \|J_r\| \cdot |\nabla v_N|
\]
\[
\cdot \left\{ \int_{\tau} \left( \|J_r^2 Q_2 J_r\|^2 + \|J_r^2 Q_3 J_r\|^3 \right) \right\}^{1/2}
\]
\[
\leq cN^{-\alpha/2} \left\{ \sum_{\tau \in T_N} \int_{\tau} \|J_{r'}^{-1}\|^4 \cdot \|J_r\|^2 \cdot \left( \|J_r^2 Q_2 J_r\|^2 + \|J_r^2 Q_3 J_r\|^3 \right) \right\}^{1/2} \cdot |\nabla v_N| L^2(\Omega),
\]
where in the second step we used the trace theorem to convert the integral on edge \( \hat{e} \) into the integral on element \( \hat{\tau} \).

Combining the estimates for \( I_1, I_2, \) and (4), we have for any \( v_N \in S_N \),

\[
|a(u - u_I, v_N)| \leq c \|\nabla v_N\| \cdot \left\{ \sum_{\tau} \int_{\tau} (1 + N^{-\alpha} \|J_\tau^{-1}\|_4^4 \|J_\tau\|^2) \cdot \|J_\tau^T Q_2 J_\tau\|^2 + \|J_\tau^{-1}\|_4^4 \|J_\tau\|^2 \cdot \|J_\tau^T Q_3 J_\tau\|^3 \right\}^{1/2},
\]

which completes the proof of (17).

Finally, by the assumption that \( \mathcal{T}_N \) is quasi-uniform under metric \( M \), we have from (10) that

\[ J_\tau \simeq (C_M N^{-1})^{1/2} F_\tau. \]

By putting it into (17) and using the continuity of \( M \), we have the error bound (18) in integral form.

**Remark 4.1.** Similar to Remark 3.1, if \( \nabla^2 u \) is positive definite on \( \Omega \), and the triangulation is quasi-uniform under metric \( M = c(\lambda_{\text{max}}/\lambda_{\text{min}})^{1/4} \cdot \nabla^2 u \), we may also derive an error bound for \( \|u_N - u_I\|_{1,\Omega} \) in terms of the eigenvalues of \( \nabla^2 u \) and \( Q_3 \). In particular, if \( \alpha < 1 \), then the leading term on the right-hand side in (18) is of magnitude \( cN^{-(1+\alpha)/2}(\|\lambda_{\text{min}}^{1/4} \lambda_{\text{max}}^{3/4}\|_{L^1(\Omega)} \cdot \|\lambda_{\text{min}}^{-3/4} \lambda_{\text{max}}^{7/4}\|_{L^1(\Omega)})^{1/2} \).

### 5. Superconvergence of Postprocessing

Let \( \mathcal{P} \) be the global \( L^2 \)-projection onto \( S_N \). We discuss in this section the superconvergence of \( \mathcal{P}(\nabla u_N) \) to \( \nabla u \). A key step leading to this result is the superconvergent error estimate for \( \|\nabla u - \mathcal{P}(\nabla u_I)\| \). To obtain this estimate, we first derive an identity for the difference \( \nabla u_q - \nabla u_I \), where \( u_q \) is the piecewise quadratic "projection based interpolation" of \( u \) defined as

\[ u_q = u_I + \sum_{k=1}^{3} \alpha_k q_k \quad \text{with} \quad \alpha_k = \frac{6}{\ell_k} \int_{e_k} (u - u_I), \]

where \( q_k = \phi_{k+1} \phi_{k-1} \) is the side basis associated with edge \( e_k \). Clearly, \( \int_{e_k} (u - u_q) = 0 \) on each edge \( e_k \). In addition, \( u_q \) is continuous on \( \Omega \), and vanishes on \( \partial \Omega \) if \( u \) does.

**Lemma 5.1.** For any \( u \) with \( u|_{\partial \Omega} = 0 \) and any \( w \in (S_N)^2 \), we have

\[
(\nabla u_q - \nabla u_I, w)_\Omega = \sum_{e_k \in \Omega} (w(m_k) \cdot n_k) \ell_k \left\{ \frac{1}{\ell_{k+1}} \int_{e_{k+1}} + \frac{1}{\ell_{k-1}} \int_{e_{k-1}} \right\} (u - u_I)
- \frac{1}{\ell_{k'}} \int_{e_{k'+1}} - \frac{1}{\ell_{k'-1}} \int_{e_{k'-1}} \right\} (u - u_I)
+ \sum_{e_k \in \partial \Omega} (w(m_k) \cdot n_k) \ell_k \left\{ \frac{1}{\ell_{k+1}} \int_{e_{k+1}} + \frac{1}{\ell_{k-1}} \int_{e_{k-1}} \right\} (u - u_I),
\]

where the summations are over all interior edges \( e_k \in \Omega \) and boundary edges \( e_k \in \partial \Omega \) in the partition, respectively. \( w(m_k) \) is the value of \( w \) at the midpoint \( m_k \) of each \( e_k \), refer to Figure 2.
Proof. By the facts that \( u|_{\partial \Omega} = 0 \) and that \( w \) is linear on each element, we have

\[
(\nabla u_q - \nabla u_I, w)_\Omega = -(u_q - u_I, \nabla \cdot w)_\Omega = - \sum_{\tau} (\nabla \cdot w|_\tau) (u_q - u_I, 1)_\tau.
\]

Note that \( (q_k, 1)_\tau = \frac{1}{12} |\tau| \), we have

\[
(u_q - u_I, 1)_\tau = (\sum_{k=1}^{3} \alpha_k q_k, 1)_\tau = \frac{|\tau|}{12} \sum_{k=1}^{3} \alpha_k = \frac{|\tau|}{2} \sum_{k=1}^{3} \frac{1}{\ell_k} \int_{e_k} (u - u_I).
\]

On the other hand, let \( w|_\tau = \sum_{k=1}^{3} w_k \phi_k \). By \( \nabla \phi_k = -(\nabla \phi_{k-1} + \nabla \phi_{k+1}) \), we have

\[
\nabla \cdot w|_\tau = \sum_{k=1}^{3} w_k \cdot \nabla \phi_k = - \sum_{k=1}^{3} w_k \cdot (\nabla \phi_{k-1} + \nabla \phi_{k+1}) = - \sum_{k=1}^{3} (w_{k-1} + w_{k+1}) \cdot \nabla \phi_k.
\]

Furthermore, by \( \nabla \phi_k = - \frac{\ell_k}{2 |\tau|} n_k \) and \( w(m_k) = \frac{1}{2}(w_{k+1} + w_{k-1}) \),

\[
(27) \quad \nabla \cdot w|_\tau = - \frac{1}{|\tau|} \sum_{k=1}^{3} \ell_k w(m_k) \cdot n_k.
\]

By putting the above equation into (25), we have

\[
(\nabla u_q - \nabla u_I, w)_\Omega = \sum_{\tau} \frac{1}{|\tau|} (u_q - u_I, 1)_\tau \cdot \sum_{k=1}^{3} \ell_k (w(m_k) \cdot n_k)|_\tau
\]

\[
= \sum_{e_k \in \Omega} (w(m_k) \cdot n_k|_\tau) \ell_k \left( \frac{1}{|\tau|} (u_q - u_I, 1)_\tau - \frac{1}{|\tau'|} (u_q - u_I, 1)_{\tau'} \right)
\]

\[
+ \sum_{e_k \in \partial \Omega} \frac{\ell_k}{|\tau|} (w(m_k) \cdot n_k|_\tau) (u_q - u_I, 1)_\tau,
\]

where in the second step we used the fact that \( n_k|_\tau = -n_k'|_{\tau'} \), and \( w \) is continuous across element edges. Finally, by putting (26) into the right-hand side of the above equation, we have formula (24). □
Theorem 5.1. Suppose that $D^2 u$ and $D^3 u$ satisfy assumption (12), and that each pair of adjacent elements in $\{T_h\}$ forms an $O(N^{-(1+\alpha)/2})$-approximate parallelogram. Then

$$\| \nabla u - P \nabla u_t \| \leq c \left\{ \sum_{\tau} \int_{\tau} \| J^{-1}_\tau \|^2 \cdot \left( N^{-\alpha} \| J^T Q_2 J \| + \| J^T Q_3 J \|^3 \right) \right\}^{1/2}$$

(28)

where $\Omega_h = \bigcup_{\tau \cap \partial \Omega \neq \emptyset} \tau$ is the union of elements next to the boundary $\partial \Omega$. In addition, if partition $T_h$ is quasi-uniform under metric $M$, then we have

$$\| \nabla u - P \nabla u_t \| \leq c N^{-1/2} \left\{ \int_{\Omega} \| F \|^2 \cdot \left( C M N^{-\alpha} \| F^T Q_2 F \|^2 + (C M)^2 \| F^T Q_3 F \|^3 \right) \right\}^{1/2}$$

(29)

where $F$ and $C_M$ are determined by $M$ as in (9) and (11).

Proof. By the triangle inequality, we have

$$\| \nabla u - P \nabla u_t \| \leq \| \nabla u - P \nabla u \| + \| P(\nabla u - \nabla u_q) \| + \| P(\nabla u_q - \nabla u_t) \| .$$

The first term on the right-hand side can be bounded by the interpolation error estimate. Note on each element $\tau$,

$$\Pi_1(\nabla u) = \hat{\Pi}_1(J^{-1}_\tau \hat{\nabla} \hat{u}) = J^{-1}_\tau(\hat{\Pi}_1 \hat{\nabla} \hat{u}).$$

Hence

$$\| \nabla u - P \nabla u \|^2 \leq \| \nabla u - \Pi_1(\nabla u) \|^2 = \sum_{\tau} \int_{\tau} \| \nabla u - \Pi_1(\nabla u) \|^2$$

$$= \sum_{\tau} |\tau| \int_{\hat{\tau}} \| J^{-1}_\tau \hat{\nabla} \hat{u} - J^{-1}_\tau(\hat{\Pi}_1 \hat{\nabla} \hat{u}) \|^2$$

$$\leq \sum_{\tau} |\tau| \int_{\hat{\tau}} \| J^{-1}_\tau \|^2 \cdot \| \hat{\nabla} \hat{u} - \hat{\Pi}_1(\hat{\nabla} \hat{u}) \|^2$$

$$\leq \sum_{\tau} |\tau| \int_{\hat{\tau}} \| J^{-1}_\tau \|^2 \cdot \| \hat{D}^3 \hat{u} \|^2$$

$$\leq \sum_{\tau} |\tau| \int_{\hat{\tau}} \| J^{-1}_\tau \|^2 \cdot \| J^T Q_3 J \|^3$$

$$= \sum_{\tau} \int_{\tau} \| J^{-1}_\tau \|^2 \cdot \| J^T Q_3 J \|^3,$$

where in the second last step, we used the assumption (12) about the anisotropic behavior of $D^3 u$. 

[License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use]
The second term on the right-hand side of (30) can also be bounded by using the error estimates for quadratic interpolation,

\[
\|P(\nabla u - \nabla u_q)\|^2 \leq \|\nabla u - \nabla u_q\|^2 = \sum_{\tau} \int_{\tau} |\nabla u - \nabla u_q|^2 \\
\leq \sum_{\tau} |\tau| \int_{\tau} \|J_{\tau}^{-1}\|^2 |\nabla \tilde{u} - \nabla \tilde{u}_q|^2 \\
\leq \sum_{\tau} |\tau| \int_{\tau} \|J_{\tau}^{-1}\|^2 |\tilde{D}^3 \tilde{u}|^2 \\
\leq \sum_{\tau} \int_{\tau} \|J_{\tau}^{-1}\|^2 \|J_{\tau} Q J_{\tau}\|^3.
\]

Now we estimate the third term \(\|P(\nabla u_q - \nabla u_\tau)\|\). By the fact that

\[
(31) \quad \|P(\nabla u_q - \nabla u_\tau)\| = \sup_{w \in (S_N)^2} \frac{|(P(\nabla u_q - \nabla u_\tau), w)|}{\|w\|} = \sup_{w \in (S_N)^2} \frac{|(\nabla u_q - \nabla u_\tau, w)|}{\|w\|},
\]

we only have to bound \(|(\nabla u_q - \nabla u_\tau, w)|\) by a certain multiple of \(\|w\|\) for any \(w \in (S_N)^2\). It follows from Lemma 5.1 that

\[
|(\nabla u_q - \nabla u_\tau, w)|
\leq \sum_{e_k \in \Omega} |w(m_k)| \ell_k \left\{ \frac{1}{\ell_{k+1}} \int_{e_{k+1}} (u - u_\tau) - \frac{1}{\ell_{k'+1}} \int_{e_{k'+1}} (u - u_\tau) \right\} \\
+ \frac{1}{\ell_{k-1}} \int_{e_{k-1}} (u - u_\tau) - \frac{1}{\ell_{k'-1}} \int_{e_{k'-1}} (u - u_\tau) \right\} \\
+ \sum_{e_k \in \partial \Omega} |w(m_k)| \ell_k \left\{ \frac{1}{\ell_{k+1}} \int_{e_{k+1}} (u - u_\tau) + \frac{1}{\ell_{k-1}} \int_{e_{k-1}} (u - u_\tau) \right\}.
\]

In order to estimate the difference between the averages of \(u - u_\tau\) on opposite edges \(e_{k+1}\) and \(e_{k'+1}\), we consider \(Q = \tau \cup \tau'\) as the image of \(\hat{Q} = [0,1]^2\) under a bilinear transform \(x = B(\xi)\). Then \(e_{k+1}\) and \(e_{k'+1}\) are the images of two opposite sides of \(\hat{Q}\), say \(\eta = 1\) and \(\eta = 0\). Furthermore, let \(\tilde{u} = u \circ B\) and \(J_Q = \frac{\partial x}{\partial \xi}\). Thus

\[
\frac{1}{\ell_{k+1}} \int_{e_{k+1}} (u - u_\tau) - \frac{1}{\ell_{k'+1}} \int_{e_{k'+1}} (u - u_\tau)
= \int_0^1 (\tilde{u} - \Pi_1 \tilde{u})(\xi, 1) \, d\xi - \int_0^1 (\tilde{u} - \Pi_1 \tilde{u})(\xi, 0) \, d\xi
= \int_0^1 \xi(\xi - 1) \frac{\partial^2 \tilde{u}}{\partial \xi^2}(\xi, 1) \, d\xi - \int_0^1 \xi(\xi - 1) \frac{\partial^2 \tilde{u}}{\partial \xi^2}(\xi, 0) \, d\xi
= \int_\tilde{Q} \xi(\xi - 1) \frac{\partial^3 \tilde{u}}{\partial \xi^2 \partial \eta}(\xi, \eta) \, d\eta d\xi.
\]

Now we bound the third order derivative in the above integral. Note that \(|D^3 \tilde{u}| \leq \sup_{|s|=1} \left| \frac{\partial^3 \tilde{u}}{\partial s^3} \right|\). By using the tensor form of the chain rule for derivatives (see, e.g., Theorem 37.1 in [9]), we have for any unit vector \(s = [s_1, s_2]^T\),

\[
\frac{\partial^3 \tilde{u}}{\partial s^3} = D^3 u(x_s, x_s, x_s) + 3D^2 u(x_s, x_s s) + Du(x_s s s).
\]
Here
\[ x_s = \frac{\partial x}{\partial s} = \frac{\partial x}{\partial \xi} \cdot s = J_\Omega s \]
and \( x_{ss} = \frac{\partial^2 x}{\partial s^2} = 0 \), since \( B \) is bilinear. By formula (3) for \( B(\xi) \),
\[ x_{ss} = \frac{\partial^2 x}{\partial s^2} = s_1 s_2 \, \mathbf{d}, \]
where \( \mathbf{d} \) is the vector connecting the midpoints of two diagonals of \( Q \). Therefore, we have
\[ |D^3 u(x_s, x_s, x_s)| \leq |D^3 u(J_\Omega s, J_\Omega s, J_\Omega s)| \leq [J_\Omega s \cdot Q_3 J_\Omega s]^{3/2} \leq \|J_\Omega^T Q_3 J_\Omega\|^{3/2} \]
and
\[ |D^2 u(x_s, x_{ss})| \leq |J_\Omega s \cdot D^2 u \, \mathbf{d}| \leq \|J_\Omega^T D^2 J_\Omega\| \|J_\Omega^{-1} \mathbf{d}\| \leq cN^{-\alpha/2}\|J_\Omega^T Q_2 J_\Omega\|, \]
where in the last step we used Lemma 2.3 under the assumption that \( Q = \tau \cup \tau' \) forms an \( O(N^{-1+\alpha}) \)-approximate parallelogram. Combining them together, we have
\[ |D^3 \hat{u}| \leq cN^{-\alpha/2}\|J_\Omega^T Q_2 J_\Omega\| + \|J_\Omega^T Q_3 J_\Omega\|^{3/2}. \]
Therefore, we may derive from (33) that
\[ \left| \frac{1}{\ell_{k+1}} \int_{\ell_{k+1}} (u - u_i) - \frac{1}{\ell'_{k+1}} \int_{\ell'_{k+1}} (u - u_i) \right| \leq \int_\tau \left( cN^{-\alpha/2}\|J_\Omega^T Q_2 J_\Omega\| + \|J_\Omega^T Q_3 J_\Omega\|^{3/2} \right) \]
\[ \leq \int_\tau \left( cN^{-\alpha/2}\|J_\Omega^T Q_2 J_\Omega\| + \|J_\Omega^T Q_3 J_\Omega\|^{3/2} \right) \cdot \det(J_\Omega^{-1}). \]
Note that
\[ \|J_\Omega^{-1} J_\Omega(\xi)\| \leq \text{const}, \quad \forall \xi \in \hat{Q}, \]
which is obviously true in the case when \( \tau \) and \( Q \) are shape regular. It is also true when they are anisotropic, because \( J_\Omega^{-1} J_\Omega \) is invariant under any affine transformation of \( Q \). Therefore,
\[ \|J_\Omega^T Q_2 J_\Omega\| \leq c \|J_\Omega^T Q_2 J_\Omega\|, \quad \text{on } \tau. \]
The term \( \|J_\Omega^T Q_3 J_\Omega\| \) can be bounded similarly. In addition,
\[ \det(J_\Omega^{-1}) \leq c \det(J_\Omega^{-1}) \leq \frac{c}{|\tau|}. \]
Hence we have
\[ \left| \frac{1}{\ell_{k+1}} \int_{\ell_{k+1}} (u - u_i) - \frac{1}{\ell'_{k+1}} \int_{\ell'_{k+1}} (u - u_i) \right| \leq \frac{c}{|\tau|} \int_\tau \left( N^{-\alpha/2}\|J_\Omega^T Q_2 J_\Omega\| + \|J_\Omega^T Q_3 J_\Omega\|^{3/2} \right). \]
Put it into (32) and note that
\[ \frac{\ell_k}{|\tau|} = \frac{4}{3\sqrt{3}} \cdot \left| \frac{J_\tau \hat{e}_k}{\det(J_\tau)} \right| \leq \frac{4}{3} \cdot \frac{\|J_\tau\|}{\det(J_\tau)} \leq \frac{4}{3} \cdot \|J_\tau^{-1}\|. \]
then we have
\[
|\nabla u_q - \nabla u_t, w| \leq c \sum_{\tau} \left( \sum_{k=1}^{3} \frac{\ell_k}{|\tau|} |w(m_k)| \right) 
\cdot \int_{\tau} \left( N^{-\alpha/2} \|J_{\tau}^T Q_2 J_{\tau}\| + \|J_{\tau}^T Q_3 J_{\tau}\|^{3/2} \right)
\]
\[
\leq c \sum_{\tau} \left( \sum_{k=1}^{3} |w(m_k)| \right) \cdot \|J_{\tau}^{-1}\| \cdot \left( N^{-\alpha/2} \|J_{\tau}^T Q_2 J_{\tau}\| + \|J_{\tau}^T Q_3 J_{\tau}\|^{3/2} \right)
\leq c \|w\| \cdot \left\{ \sum_{\tau} \|J_{\tau}^{-1}\|^2 \cdot \left( N^{-\alpha} \|J_{\tau}^T Q_2 J_{\tau}\|^2 + \|J_{\tau}^T Q_3 J_{\tau}\|^3 \right) \right\}^{1/2},
\]
where we have used the fact that
\[
\int_{\tau} \left( \sum_{k=1}^{3} |w(m_k)| \right)^2 \leq c \int_{\tau} |w|^2.
\]
This completes the estimate for the first sum on the right-hand side of (32).

For the second sum on the right-hand side of (32) involving edges on the domain boundary, note that \( u - u_t = 0 \) on \( \partial \Omega \), thus we have for any linear function \( p_1 \),
\[
\left| \frac{1}{\ell_{k+1}} \int_{e_{k+1}} (u - u_t) + \frac{1}{\ell_{k-1}} \int_{e_{k-1}} (u - u_t) \right| = \int_{\partial \varphi} \left| \hat{u} - \hat{u}_t \right| 
\leq c \|\hat{u} + p_1\|_{H^2(\varphi)} \leq c \|\hat{u}\|_{H^2(\varphi)}
\]
Since \( p_1 \) is arbitrary, it follows from Bramble-Hilbert Lemma [9] that
\[
\left| \frac{1}{\ell_{k+1}} \int_{e_{k+1}} (u - u_t) + \frac{1}{\ell_{k-1}} \int_{e_{k-1}} (u - u_t) \right| \leq c \inf_{p_1} \|\hat{u} + p_1\|_{H^2(\varphi)} \leq c \|\hat{u}\|_{H^2(\varphi)}
= c \left\{ \int_{\varphi} |\nabla^2 \hat{u}|^2 \right\}^{1/2}
\leq c \left\{ \int_{\varphi} \|J_{\tau}^T Q_2 J_{\tau}\|^2 \right\}^{1/2}.
\]
Therefore, we have
\[
\sum_{e_k \in \partial \Omega} |w(m_k)| \ell_k \left\{ \left| \frac{1}{\ell_{k+1}} \int_{e_{k+1}} (u - u_t) + \frac{1}{\ell_{k-1}} \int_{e_{k-1}} (u - u_t) \right| \right\}
\leq c \sum_{e_k \in \partial \Omega} |w(m_k)| |\tau|^{1/2} \cdot \left\{ \int_{\varphi} \|J_{\tau}^T Q_2 J_{\tau}\|^2 \right\}^{1/2}
\leq c \left\{ \sum_{e_k \in \partial \Omega} |w(m_k)|^2 |\tau| \right\}^{1/2} \cdot \left\{ \sum_{\tau \in \Omega_h^b} \int_{\tau} \|J_{\tau}^{-1}\|^2 \|J_{\tau}^T Q_2 J_{\tau}\|^2 \right\}^{1/2}
\leq c \|w\| \cdot \left\{ \sum_{\tau \in \Omega_h^b} \int_{\tau} \|J_{\tau}^{-1}\|^2 \|J_{\tau}^T Q_2 J_{\tau}\|^2 \right\}^{1/2}.
\]
By combining (34) and (35), we complete the estimate of the right hand side of (32), and hence the proof of (28).

The proof of (28) is similar to that of [11].
By using Theorems 4.1 and 5.1, and the triangle inequality
\begin{equation}
\|\nabla u - \mathcal{P}\nabla u_N\| \leq \|\nabla u - \mathcal{P}\nabla u_I\| + \|\mathcal{P}(\nabla u_N - \nabla u_I)\|
\end{equation}
we have immediately the following result on the superconvergence of the post-processed finite element solution.

**Theorem 5.2.** Under the same assumption of Theorem 5.1, we have
\begin{equation}
\|\nabla u - \mathcal{P}\nabla u_N\| \leq c \left\{ \sum_{\tau} \int_{\tau} (1 + N^{-\alpha} \|J_\tau^{-1}\| \|J_\tau\|^{2}) \cdot \|J_\tau^T Q_2 J_\tau\|^{2} \right. \\
+ \|J_\tau^{-1}\| \|J_\tau\|^{2} \cdot \|J_\tau^T Q_3 J_\tau\|^{3} \right\}^{1/2} \\
+ \left. c \left\{ \sum_{\tau \in \Omega_h} \int_{\tau} \|J_\tau^{-1}\|^{2} \cdot \|J_\tau^T Q_2 J_\tau\|^{2} \right\}^{1/2} .
\end{equation}

In addition, if the partition $\mathcal{T}_h$ is quasi-uniform under metric $M$, then
\begin{equation}
\|\nabla u - \mathcal{P}\nabla u_N\| \leq c N^{-1/2} \left\{ \int_{\Omega} ((C_M)^2 N^{-1} + C_M N^{-\alpha/2} \|F^{-1}\| \|F\|^{2}) \cdot \|F^T Q_2 F\|^{2} \right. \\
+ \left. \|F^T Q_3 F\|^{3} \right\}^{1/2} \\
+ cN^{-1/2} \left\{ C_M \int_{\Omega_h} \|F^{-1}\|^{2} \cdot \|F^T Q_2 F\|^{2} \right\}^{1/2} .
\end{equation}

**Remark 5.1.** In practical computation, the mesh metric $M$ is typically chosen to be a certain scalar multiple of $Q_2$. In this case, the integrals in (37) involving elements next to the domain boundary are only an $O(N^{-1/2})$ portion of the same integral over the entire $\Omega$, and the second integral in (38) is of order $O(N^{-1/2})$, which implies $\|\nabla u - \mathcal{P}\nabla u_N\|$ converges at the rate of $O(N^{-1+\min(1,\alpha)/2})$. It also implies the asymptotic exactness (as $N \to \infty$) of the error estimator $\|\nabla u_N - \mathcal{P}\nabla u_N\|$ for solutions satisfying condition $\|\nabla u - \nabla u_N\| \geq cN^{-1/2}$.

**Remark 5.2.** Comparing the estimates for $\|\nabla u_N - \nabla u_I\|$ in Theorem 4.1 and $\|\nabla u - \mathcal{P}(\nabla u_I)\|$ in Theorem 5.1, we note that there is an extra factor $\text{cond}(J_\tau) = \|J_\tau\| \|J_\tau^{-1}\|$ for the bound of the former. This factor measures the aspect ratio of $\tau$. Thus for highly anisotropic meshes, $\|\nabla u_N - \nabla u_I\|$ can be much larger than $\|\nabla u - \mathcal{P}(\nabla u_I)\|$, even though both of them are of the same convergence rate. This is a new feature not existing in the superconvergence estimates on isotropic meshes. We believe this extra factor is not due to the technical treatment in our analysis, but rather the fact that $\|\nabla u_N - \nabla u_I\|$ is basically the $H^1$-norm of the $H^1$-projection of $u - u_I$, while $\|\nabla u - \mathcal{P}(\nabla u_I)\|$ is mainly the $L^2$-error of an $L^2$-projection. While $L^2$-projection is insensitive to the aspect ratio of elements, $H^1$-projection is not. Numerical results in the next section seem to support this observation.

6. Numerical results

We present in this section some numerical results for the linear finite element solution and its error estimates of the model problem. We choose in $\Omega = [0, 1]^2$, and the coefficients $A = I_2$, $b = 0$, $d = 1$. The right-hand side function $f$ and the Dirichlet boundary condition are selected so that \[ admits the following exact solutions:
Example (1). \( u(x, y) = \tanh[-50(r - 0.3)] \), where \( r \) is the distance to the center of \( \Omega \).

Example (2). \( u(x, y) = \frac{\cosh(kx) + \cosh(ky)}{2 \cosh(k)} \) with \( k = 50 \).

The first example involves an internal layer along a circle in the domain, while the second one a boundary layer along the top and right sides of the domain.

To obtain the adaptive meshes and the finite element solutions, we start with a Delaunay triangulation of \( \Omega \), and calculate the finite element solution based on it. Then we recover the second order derivatives of the solution, and define a mesh metric on \( \Omega \). We use a two-dimensional anisotropic generator, \textsf{bamg} \[13\], to create an adaptive mesh that is quasi-uniform under the mesh metric, and calculate again the finite element solution based on the adaptive mesh. This process is repeated 20 times, which is hand-picked but seems sufficient to obtain a convergent mesh and the finite element solution. In practical computation, more judicious criterions, e.g., a threshold on the differences between the meshes or solutions in consecutive iterates, should be applied to control this iterative process.

In order to defined the mesh metrics, we first approximate the second derivatives \( \nabla^2 u \) by
\[
\tilde{H} = \nabla (P(\nabla u_N)),
\]
where \( P \) is the \( L^2 \)-projection onto \( S_N \). We choose here the \( L^2 \)-projection of \( u_N \) because it is the quantity involved in our analysis; see Theorem 5.2. Other types of postprocessing, e.g., local averaging, are also possible. Since \( \tilde{H} \) is piecewise constant, it is further approximated by a continuous piecewise linear function, still denoted by \( \tilde{H} \), with the nodal values equal to the weighted average over the element patch around each node. The anisotropic behavior of \( \nabla^2 u \) is then characterized by
\[
Q_2 = \text{abs}(\tilde{H}) + \delta I,
\]
where \( \text{abs}(\tilde{H}) \) is the matrix of the same eigenvectors as \( \tilde{H} \), but with eigenvalues the absolute value of \( \tilde{H} \)'s. \( \delta \geq 0 \) is a user defined parameter to avoid the mesh metric based on it being singular in case \( \nabla^2 u \) becomes singular. A smaller \( \delta \) makes \( Q_2 \) a more precise characterization of the anisotropic behavior of \( \nabla^2 u \) and the mesh metric more effective, while a larger \( \delta \) results in a less aggressive anisotropic refinement and is easier for refinement. An optimal value of \( \delta \) is problem dependent and should be selected dynamically. However, this is not our main objective in this paper. We choose for simplicity in all our numerical examples \( \delta = 1 \) (a small value compared to the magnitude of the second derivatives of \( u \)).

The mesh metric \( M \) is then defined as in \[5,7\] for the minimization of the \( H^1 \)-error for the linear interpolation of \( u \) on anisotropic meshes,
\[
M = c \left[ \frac{\lambda_{\max}}{\lambda_{\min}} \right]^{1/4} Q_2,
\]
where \( \lambda_{\max} \) and \( \lambda_{\min} \) are the largest and smallest eigenvalues of \( Q_2 \), and \( c \) is a constant to control the total number of elements.

In order to check the \( O(N^{-\left(1+\alpha\right)/2}) \)-approximate parallelogram property for the adaptive meshes used in our computation, we introduce a quantity \( \mathcal{H}_{ap} \) to measure how close a pair of adjacent elements is to a parallelogram. Suppose \( \tau_1 \) and \( \tau_2 \) share a common edge \( e \). \( J_1 \) and \( J_2 \) are the Jacobian of the affine mapping from an equilateral standard element \( \hat{\tau} \) to \( \tau_1 \) and \( \tau_2 \), respectively, with the two vertices...
opposite to \(e\) being the images of the same vertex of \(\hat{\tau}\). Define
\[
\mathcal{M}_{ap}(e) = \frac{1}{2} \left( \| I + J_1^{-1} J_2 \| + \| I + J_2^{-1} J_1 \| \right),
\]
where the matrix norm is chosen to be Frobenius norm for easy calculation. Note that when \(\tau_1\) and \(\tau_2\) form an \(O(N^{-(1+\alpha)/2})\)-approximate parallelogram, both terms on the right-hand side of (41) are of magnitude \(O(N^{-\alpha/2})\) (see Section 2), thus \(\mathcal{M}_{ap} = O(N^{-\alpha/2})\). We use their average in (41) to produce a measurement symmetric for both sides of an edge. As noted in Lemma 2.2, this measure is invariant under any affine mapping of the element pair. When \(\tau_1\) and \(\tau_2\) form an exact parallelogram, \(\mathcal{M}_{ap}(e_k) = 0\). When they are congruent but form a triangle, \(\mathcal{M}_{ap} = 2\sqrt{2}/3 \approx 1.155\). If \(\tau_1\) is shape regular but \(\tau_2\) is of a high aspect ratio, then \(\mathcal{M}_{ap} >> 1\).

We notice that Bank and Xu established in [3] the convergence of \(\tilde{H}\) (with some additional smoothing steps to improve the convergence rate) to \(\nabla^2u\) for quasi-uniform meshes. In the case of adaptive anisotropic meshes, there is no such theory yet, even though the idea of using \(\tilde{H}\) for mesh refinement has been in practice for a long time; see, e.g., [8, 10–12]. When \(\tilde{H}\) is a good approximation of \(\nabla^2u\), the above defined mesh metric will be optimal for minimizing the \(H^1\) semi-norm of the interpolation error, and thus for minimizing the a priori bound of the finite element solution error as stated in Theorem 3.1.

We examine the following quantities involved at various stages of our analysis:
\[
E_{uN} = \| \nabla u - \nabla u_N \|, \quad E_{pN} = \| \nabla u - P(\nabla u_N) \|,
\]
\[
E_{puN} = \| \nabla u - P(\nabla u_N) \|, \quad E_{puN} = \| \nabla u - P(\nabla u_N) \|,
\]
\[
E_{pNI} = \| P(\nabla u_N - \nabla u_I) \|.
\]
In addition, we check the effectivity factor \(\eta\) of the error estimator \(E_{NpN}^\#\):
\[
\eta = \frac{E_{NpN}^\#}{E_{uN}}.
\]
For each of the above errors \(E\) and \(|\eta - 1|\), we estimate its rate of convergence \(\beta\) by linear regression of \(\ln E\) vs. \(\ln(1/\sqrt{N})\), i.e.,
\[
E \approx cN^{-\beta/2}.
\]

For comparison, we also report the results for solutions based on uniform meshes obtained from bisecting uniform square meshes on \(\Omega\) with the 135° diagonals. Note that these uniform meshes can be considered as quasi-uniform under mesh metric \(I\) and each pair of the adjacent elements forms an \(O(N^{-(1+\alpha)/2})\)-approximate parallelogram with \(\alpha = \infty\). In this case, \(E_{NI}\) will be of order \(N^{-1}\) according to Theorem 4.1, and \(E_{puI}\) and \(E_{pNI}\) will also be of order \(N^{-1}\) in the absence of boundary errors according to Theorems 5.1 and 5.2.

We list in Tables 1 and 2 the results for Example (1) with adaptive and uniform meshes, respectively, and Tables 3 and 4 for Example (2) similarly. Clearly, in all the cases, \(E_{uN}\) converges linearly, i.e., at the rate of \(O(N^{-1/2})\), and the effectivity factor \(\eta \rightarrow 1\), which indicates that the error estimator \(E_{NpN}^\#\) is asymptotically exact. In addition, \(E_{NI}\) converges quadratically on uniform meshes as predicted in Theorem 4.1 with \(\alpha = \infty\). On adaptive meshes, the superconvergence of \(E_{NI}\) is much weaker, with \(\alpha \approx 0.12\) only. This result is similar to that reported in [3] for the case of adaptive meshes composed of shape regular elements. The slower convergence rate with adaptive meshes results mainly from the fact that there are elements in the triangulation that do not form approximate parallelograms due to

geometric constraints, or the approximate parallelograms are rather poorly shaped; see Figure 3 and Figure 6 for a close-up look of typical meshes. Strictly speaking, these meshes belong to a more general type satisfying the so-called condition \((\alpha, \sigma)\) introduced in [30] for shape regular meshes; namely, most element pairs in the partition form \(O(N^{-1+\alpha/2})\)-approximate parallelograms and the measure of those that do not is at most \(O(N^{-\sigma/2})\). The extension of our analysis to this type of meshes is straightforward. We choose not to include it here for the purpose of

simplifying our presentation. Instead, we report some statistics about the measurement $\mathcal{M}_{ap}$ for how close each pair of elements is to a parallelogram. We display in Figure 4 and Figure 7 the distribution of $\mathcal{M}_{ap}$ for a typical adaptive mesh generated by bamg in Examples (1) and (2), respectively. To further quantify this distribution, we plot in Figure 5(a) and Figure 8(a) the percentile of the element pairs whose $\mathcal{M}_{ap}$ are below a given value for each of the adaptive meshes reported in Table 1 and Table 3. It is clear from these two figures that as the mesh gets refined by bamg, $\mathcal{M}_{ap}$ decreases in general, and more and more element pairs become closer and closer to exact parallelograms. We plot in Figure 5(b) and Figure 8(b) the average value, $\overline{\mathcal{M}}_{ap}$, of $\mathcal{M}_{ap}$ over the entire mesh for each of the adaptive meshes. Based on linear regression of $\ln \mathcal{M}_{ap}$ vs. $\ln N$, we find that $\mathcal{M}_{ap} \approx O(N^{-\bar{\alpha}/2})$ with $\bar{\alpha} = 0.208$ and 0.278 for the adaptive meshes generated by bamg in Example (1) and Example (2), respectively.

It is also noted that $E_{pu_{I}}$ exhibits superconvergence for both examples and both types of meshes as described in Theorem 5.1. However, with uniform meshes, the convergence rate is about $O(N^{-1})$ for Example (1) and $O(N^{-1.387/2})$ for Example (2). We believe the loss of the convergence rate in Example (2) is due to the boundary term in (28). Note that the solution of Example (1) is nearly 0 around the boundary of $\Omega$, while it it not the case for Example (2). With adaptive meshes, $E_{pu_{I}}$ converges at a rate $O(N^{-1.485/2})$ for both examples, and the effect of boundary terms for Example (2) seems to be masked by that of non-ideal approximate parallelograms.

By comparing $E_{pu_{I}}$ to $E_{NI}$, we note that on uniform meshes $E_{NI}$ is always smaller than $E_{pu_{I}}$, while on adaptive meshes it is the other way around. This phenomenon reflects their dependence on the element aspect ratio stated in Remark 5.2; namely, higher element aspect ratios have a stronger negative impact on the accuracy of $E_{NI}$ than on $E_{pu_{I}}$. On the other hand, for both examples on adaptive meshes, $E_{pu_{I}}$ seems to behave very similarly to $E_{pu_{N}}$, even though the bound for the latter involves an extra factor of the element aspect ratio $\text{cond}(F_{\tau})$; see Theorems 5.1 and 5.2. It raises the question of whether this extra factor in the bound for $E_{pu_{N}}$ is indeed necessary. In our analysis this extra factor is introduced due to the use of triangle inequality (36), which relies on the estimate (17) of $E_{NI}$. Unfortunately, we still do not know if it is possible not to use $E_{NI}$ to provide $E_{pu_{N}}$ with a similar bound as for $E_{pu_{I}}$. 

Figure 3. Example (1): Left: An adaptive mesh generated by \texttt{bamg} based on metric (40) with the total number of elements $N = 4070$. Right: Its close-up look.

Figure 4. Example (1): Left: The distribution of measure $\mathcal{M}_{ap}$ defined in (41) for the closeness of a pair of adjacent elements to a parallelogram, on the adaptive mesh with $N = 4070$. The color around an edge $e$ represents the magnitude of $\mathcal{M}_{ap}(e)$ for the pair sharing $e$. Right: Its close-up look.
Figure 5. Example (1): Left: Percentile curves for the number of element pairs whose $M_{ap}$ are below a given value specified by the horizontal axis. The 7 curves from the bottom up represent the 7 adaptive meshes reported in Table 1 in increasing order of $N$. Right: The average value of $M_{ap}$ vs. the number $N$ of elements for each of the adaptive meshes.

Figure 6. Example (2): Left: An adaptive mesh generated by bamg based on metric (40) with the total number of elements $N = 4030$. Right: Its close-up look.
Figure 7. Example (2): Left: The distribution of measure $M_{ap}$ defined in (41) for the closeness of a pair of adjacent elements to a parallelogram, on the adaptive mesh with $N = 4050$. The color around an edge $e$ represents the magnitude of $M_{ap}(e)$ for the pair sharing $e$. Right: Its close-up look.

Figure 8. Example (2): Left: Percentile curves for the number of element pairs whose $M_{ap}$ are below a given value specified by the horizontal axis. The 7 curves from the bottom up represent the 7 adaptive meshes reported in Table 3 in increasing order of $N$. Right: The average value of $M_{ap}$ vs. the number $N$ of elements for each of the adaptive meshes.
7. Conclusion and discussions

For the linear finite element method based on adaptive anisotropic meshes in two dimensions, we established the superconvergence of the finite element solutions to the interpolation of exact solutions in energy norm. We also proved the superconvergence of the recovery process using the global $L^2$-projection of the gradients of the finite element solutions. Our analysis is based on the notion that the mesh is quasi-uniform under a Riemannian metric and the notion that each adjacent element pair forms an approximate parallelogram. These notions are extensions of the corresponding concepts in classical superconvergence studies on meshes composed of shape regular elements. In particular, our analysis follows the same methodology developed in Bank and Xu [3] for the case of quasi-uniform meshes, and can be viewed as an extension of their conclusion to the case of unstructured anisotropic meshes. Numerical examples involving both internal and boundary layers are in support of these superconvergence properties.

It should be noted that our analysis is concerned with the asymptotic behavior of the solution and its post-processing. Therefore, the conclusion is meaningful only when the mesh is sufficiently fine for the underlying problem. In the initial stages of an adaptive finite element solution where mesh resolution is far from enough, the error from data approximation can be more pronounced and the error estimates based on post-processing may not be accurate. In this case, except the anisotropic behavior of the PDEs is known a-priori, one should be extremely careful about the use of anisotropic coarse meshes, since a highly anisotropic element may introduce a much larger error than an isotropic element does if used inappropriately. Therefore, it is generally advised to begin an adaptive process with isotropic coarse meshes and other types of error estimators should be considered, too.

Several issues remain unresolved in this paper. First, it is observed in numerical experiments that the convergence of $\|\nabla u - P(\nabla u_N)\|$ is similar to $\|\nabla u - P(\nabla u_I)\|$ and both are less sensitive to high element aspect ratio than $\|\nabla u_N - \nabla u_I\|$. However, the estimate for $\|\nabla u - P(\nabla u_N)\|$ involves an extra factor of the element aspect ratio than the one for $\|\nabla u - P(\nabla u_I)\|$. It seems a sharper analysis tool is needed to remove this extra factor if it is indeed non-essential.

Second, with unstructured adaptive meshes the superconvergence for both $\|\nabla u_N - \nabla u_I\|$ and $\|\nabla u - P(\nabla u_N)\|$ is rather weak due to the non-uniformity of the elements. Bank and Xu proposed in [4] to reduce the dependence on mesh uniformity and strengthen the superconvergence of the gradient recovery by employing several cycles of multigrid type smoothing in addition to the $L^2$-projection. Their numerical results showed such a treatment may improve the superconvergence substantially. This idea is yet to be tested for the case of anisotropically refined meshes. Furthermore, we hope that with the improved superconvergence property for the recovered gradients the convergence for the approximation of $\nabla^2 u$ by $\tilde{H}$ in (39) can be established in the case of anisotropic meshes.

There are several other types of gradient recovery techniques used in practice. The most popular one is probably Zienkiewicz-Zhu’s superconvergence patch recovery (SPR) based on local averaging [36,37], and a more recent variation, the polynomial preserving recovery (PPR), by Zhang [23,32,34] based on higher order local approximation of the solution. There has been extensive work on the analysis of these techniques on uniform meshes, structured and unstructured isotropic
meshes [15,30], and recently on structured anisotropic meshes [32]. With the establishment of the superconvergence of \( \| \nabla u_N - \nabla u_I \| \), it is now possible to establish the superconvergence of these local gradient recovery techniques on general adaptively refined anisotropic meshes. We will report a detailed analysis and numerical results for these techniques in a separate paper.
