ABSTRACT

Cloud computing is a BUZZ word of modern computing scenario. Cloud computing services are flexible and cost effective with resource utilization. Cloud computing have three service models SaaS (Software as a Service) PaaS (Platform as a Service) and IaaS (Infrastructure as a Service). SaaS provide on demand application services such as email, ERP and CRM etc. Multi user can access applications and they can interact to each other at same time. All users data can be reside at same place. This flexibility of SaaS service also gives the security breaches. Loop holes of SaaS harder to find and maintain. The authors discuss here security vulnerabilities of SaaS with possible solutions. This study would be helpful to elaborate to understand data security issues and privacy solutions over SaaS.

Keywords: Security, Security as a Service (SaaS), Security Assertion Markup Language (SAML), Secure Socket Layer (SSL), Transport Layer Security (TLS)

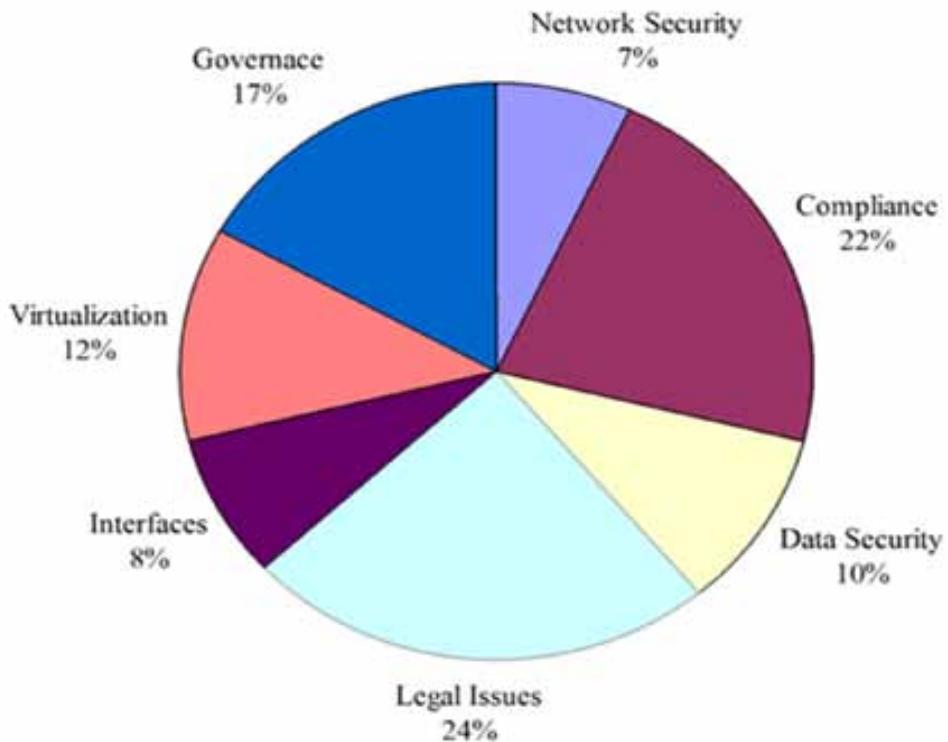

1. INTRODUCTION

In new computing paradigm cloud computing is most popular cost effective, flexible, highly available, pay per use computing web based service, which provides three service models (SaaS (Software as a Service), PaaS (Platform as a Service), IaaS (Infrastructure as a Service)) four Deployment model (Private, Public, Hybrid, and Community) and five essential characteristics (On demand self service, Broad network access, Resource pooling, Rapid elasticity, Measured service) (Jansen, 2011; Paul, 2014; Tiwari, 2012).

Traditional storage, data management scheme is not superior enough to store and analyzing the big data. Cloud virtual information framework system has the capacity to handle the enormous information issue, yet it is insufficient great in security of information (Hassanien et al., 2015). Providers to ensure robust security system to users. Service providers used third party security and security audit systems. Service providers provide security, SecaaS (Security as a Service). SecaaS includes authentication, antivirus, anti malware, intrusion detection and security management at different level. SecaaS control the data loss

prevention, web security, encryption, network security and disaster recovery (Alliance, 2011b; Pearson, 2013).

Cloud Users can access computing resources via internet. Security is the main concern for cloud users. Security is divided mainly into seven categories (a) Legal issues (b) Network (c) Interface (d) Information (data security) (e) Compliance (f) Virtualization and (g) Governance (Gonzalez et al., 2012).

The Result shows the legal issues and compliance are major security issues as shown in Figure 1. Pie chart shows virtualization has greater security vulnerabilities than network security. Virtualization gives the elasticity, resource pooling and multi tenancy facility in cloud computing (David, 2009; Luo, 2011).

Amazon AWS provides EC2 (Elastic Cloud Computing) and S3 (Simple Storage Service) with secure system. Amazon AWS uses

multiple third party authorized audit security system (ISO/IES-27002 control framework). Salesforce.com provides secure SaaS services with CRM (Customer Resource Management) features. HP, IBM, Google, Windows Azure also gives security assurance to users (Amazon, 2014; Azure, 2014; Somorovsky et al., 2011).

Cloud providers take care on network security, IT system (system security), information (data security) and application security. Security responsibility ensures from client side and server side (Ma, 2012). Service provider provides several new security trends, but they are still not providing full robust security mechanism till now. Amazon AWS EC2 offers physical security, environmental security and virtualization security. Salesforce.com CRM (Customer Resource Management) offers security responsibilities in physical and environmental security control. Microsoft AZURE uses token based
