Abstract—In this paper, for an integer $k$, we evaluate an upper bound for the cross-correlation of a ternary $m$-sequence of period $N = 3^4k^2+2 - 1$ and its decimated sequence with decimation $d = \frac{3^4k^2+2 - 3^{2k+1}+2 + 3^{2k+1}}{4}$. It is found that the cross-correlation is upper bounded by $4.5 \cdot 3^{2k+1} + 1$.

Index Terms—Cross-correlation, decimation, exponential sum, $m$-sequence, quadratic form

I. INTRODUCTION

The cross-correlation between $p$-ary $m$-sequences and their decimated sequences by $d$ has been extensively studied by many researchers. Trachtenberg [1] investigated the cross-correlation for the decimation $d = \frac{p^2-2}{2}$ and $d = p^2 - p^k + 1$ when $p$ is an odd prime. Helleseth [2] summarized many known results and evaluated cross-correlation distributions for various values of decimations. Muller [3] proved that for odd $n$, the cross-correlation between a ternary $m$-sequence and its decimation by $d = \frac{3^n+1}{3+1} \cdot \frac{3^n-1}{2}$ is upper bounded by $2\sqrt{n^3}$.

Hu et al. [4] generalized Muller’s result to $p = 3$ mod 4, and Xia, Zeng, and Hu [5] have evaluated the correlation distribution. More recently, Ness and Helleseth, Kholosha [6] derived the distribution of the cross-correlation values for $p = 3, d = \frac{3^n+1}{3+1}$, where $k$ is an odd integer with $\gcd(k, n) = 1$. For an odd prime $p$, even $n$, and $d = p^k + 1$ with $\gcd(n, k) = 1$. Seo, Kim, No, and Shin [7] estimated the upper bound $1 + p\sqrt{n^3}$.

Choi, Lim, No, and Chung [8] investigated cross-correlation values for an odd prime $p$ and decimation $d = \frac{(p^n+1)^2}{2(p+1)}$, where $m$ is odd. For a more detailed overview on this subject, we refer the reader to [9].

In this paper, for an integer $k$, we derived an upper bound for the cross-correlation of a ternary $m$-sequence of period $3^4k^2+2 - 1$ and its decimation with $d = \frac{3^4k^2+2 - 3^{2k+1}+2 + 3^{2k+1}}{4}$. It is shown that the upper bound is given as $4.5 \cdot 3^{2k+1} + 1$. For the derivation, we use the quadratic form theory as in [3]-[8], but in this case four quadratic forms are involved. To obtain possible rank combinations of quadratic forms, Blauer’s result [10], [11] is employed. It is shown that quadratic forms have only even ranks and among four quadratic forms, at most one of them have the lowest rank.

The remainder of this paper is organized as follows. In Section II, we present preliminaries and notations. In Section III, we investigate the upper bound for the cross-correlation magnitude. Some discussion and a conjecture on the cross-correlation value is proposed in Section IV. Finally, concluding remarks are given in Section V.

II. PRELIMINARIES

A. Trace Functions and Cross-Correlation Functions

Let $p$ be a prime and $n$ be an integer. Let $\mathbb{F}_{p^n}$ be the finite field with $p^n$ elements. The trace function $\text{tr}_n^1 : \mathbb{F}_{p^n} \to \mathbb{F}_p$ is defined as

$$\text{tr}_n^1(x) = x + x^p + x^{p^2} + ... + x^{p^{n-1}}.$$ A $p$-ary $m$ sequence $s(t)$ is defined to be

$$s(t) = \text{tr}_n^1(\alpha^t)$$

where $\alpha$ is a primitive element of $\mathbb{F}_{p^n}$.

Let $\omega$ be a $p$-th root of unity in the complex field $\mathbb{C}$ and $a(t), b(t)$ be sequences over $\mathbb{F}_p$ of period $N$. Then the cross-correlation function $C(\tau)$ between $a(t)$ and $b(t)$ at time shift $\tau$ is defined as

$$C(\tau) = \sum_{t=0}^{N-1} \omega^{a(t) - b(t+\tau)}.$$ B. Quadratic Forms and Linearized Polynomials

A quadratic character $\eta(x)$ of $\mathbb{F}_{p^n}$ is defined as

$$\eta(x) = \begin{cases} 1 & \text{if } x \text{ is a nonzero square in } \mathbb{F}_{p^n} \\ -1 & \text{if } x \text{ is a nonzero nonsquare in } \mathbb{F}_{p^n} \\ 0 & \text{if } x = 0. \end{cases}$$

A quadratic form over $\mathbb{F}_p$ with $n$ indeterminates $x_1, x_2, ..., x_n$ is a homogeneous polynomial of degree 2 in $\mathbb{F}_{p^n}[x_1, x_2, ..., x_n]$, which can be expressed as

$$f(x_1, x_2, ..., x_n) = \sum_{i,j=1}^{n} a_{ij}x_ix_j.$$
where \( a_{ij} \in \mathbb{F}_p \). The matrix \( A = (a_{ij}) \) is called a coefficient matrix of \( f \), and \( \det(f) = \Delta \) is defined to be \( \det(A) \). If the rank of \( A \) is \( k \) for some \( 0 \leq k \leq n \), then we say that the rank of \( f \) is also \( k \). If rank \( (f) = n \), \( f \) is said to be nondegenerate.

For a nondegenerate quadratic form \( f \) over \( \mathbb{F}_p \), one can calculate the number of solutions of \( f(x_1, x_2, ..., x_n) = b \) for \( b \in \mathbb{F}_p \) by the following lemma.

**Lemma 1:** [12] Let \( \eta \) be the quadratic character of \( \mathbb{F}_p \). The number of solutions \( N(b) \) of \( f(x_1, x_2, ..., x_n) = b \) in \( \mathbb{F}_p^n \), when \( f \) is a nondegenerate quadratic form in rank \( n \) with determinant \( \Delta \) and \( b \in \mathbb{F}_p \), is given as follows:

Case 1) \( n \) even;

\[
N(b) = \begin{cases} 
  p^{n-1} - \epsilon p^{n/2}, & \text{if } b \neq 0 \\
  p^{n-1} - \epsilon (p-1)p^{n/2}, & \text{if } b = 0 
\end{cases}
\]

where \( \epsilon = \eta((-1)^{n/2} \Delta) \).

Case 2) \( n \) odd;

\[
N(b) = \begin{cases} 
  p^{n-1} + \epsilon(b)p^{n/2}, & \text{if } b \neq 0 \\
  p^{n-1}, & \text{if } b = 0 
\end{cases}
\]

where \( \epsilon = \eta((-1)^{(k-1)/2} \Delta) \).

From Lemma 1, the following lemma is easily derived.

**Lemma 2:** [6] Let \( \eta \) be the quadratic character of \( \mathbb{F}_3 \). Let \( f \) be a nondegenerate quadratic form in \( n \) variables with determinant \( \Delta \) and \( \omega \) be the 3rd root of unity. Then \( S = \sum_{x \in \mathbb{F}_3^n} \omega f(x) \) is given by

\[
S = \begin{cases} 
  e^{3n/2}, & \text{if } n \text{ is even} \\
  e^{i3n/2}, & \text{if } n \text{ is odd} 
\end{cases}
\]

where \( \epsilon = \eta((-1)^{n/2} \Delta) \) for even \( n \) and \( \epsilon = \eta((-1)^{(n-1)/2} \Delta) \) for odd \( n \).

For the case of rank \( f = k < n \), we can obtain the number of solutions by multiplying the result of Lemma 1 or Lemma 2 by \( p^{n-k} \). The rank of the quadratic form can be determined by the following lemma.

**Lemma 3:** [3] Let \( f \in \mathbb{F}_p[x_1, x_2, ..., x_n] \) be a quadratic form. Define

\[
Z = \{ z \in \mathbb{F}_p^n : f(x + z) - f(x) = 0 \text{ for all } x \in \mathbb{F}_p^n \}.
\]

Then \( Z \) is a subspace of \( \mathbb{F}_p^n \) and \( \text{rank}(r) = n - \dim(Z) \).

Let \( q \) be a prime power and \( m \) be an integer. A polynomial of the form

\[
L(x) = \sum_i a_i x^i
\]

with coefficients in \( \mathbb{F}_q^m \) is called a linearized polynomial over \( \mathbb{F}_q^m \). For an extension field \( F \) of \( \mathbb{F}_q^m \), we have

\[
L(x + y) = L(x) + L(y), \text{ for all } x, y \in F \\
L(cx) = cL(x), \text{ for all } x \in F \text{ and } c \in \mathbb{F}_q.
\]

Thus the set of roots of a linearized polynomial is a vector space over \( \mathbb{F}_q \) and the number of roots is a power of \( q \).

**C. Number of Solutions of** \( x^{p^{r+1}} - cx + c \)

The following lemmas will be used to determine the number of solutions of some linearized polynomials.

**Lemma 4:** [10] [11] Let \( h_c(x) = x^{p^{r+1}} - cx + c \), \( c \in \mathbb{F}_p^* \). Then \( h_c(x) = 0 \) has either 0, 1, 2, or \( p \gcd(s,n) + 1 \) roots in \( \mathbb{F}_p^n \).

**Lemma 5:** [10] Let \( F \) be a finite field of characteritic \( p \) and \( c \in F^* \). Suppose \( q \) is a power of \( p \) and \( F \cap \mathbb{F}_q = \mathbb{F}_q \). Define \( f(x) = x^{p^{r+1}} - cx + c \). Then the following are equivalent.

1) \( f \) has at least three roots in \( F \);
2) \( f \) has exactly \( Q + 1 \) roots in \( F \);
3) \( f \) has at least two roots in \( F \) and \( N_{F/F_q}(r-1) = 1 \) for all root \( r \) in \( F \).

By setting \( F = \mathbb{F}_{p^{nk+2}}, q = p^k \) in Lemma 5, we have the following result.

**Corollary 6:** Let \( k \) be an integer, \( n = 4k + 2 \), and \( p \) be an odd prime. Then \( \mathbb{F}_{p^n} \cap \mathbb{F}_{p^k} = \mathbb{F}_{p^k} \). Let \( f(x) = x^{p^{r+1}} - cx + c \), \( c \in \mathbb{F}_{p^n} \). Then the following are equivalent.

1) \( f \) has exactly \( p^2 + 1 \) roots in \( \mathbb{F}_{p^n} \);
2) \( f \) has at least two roots in \( \mathbb{F}_{p^k} \) and

\[
(r-1)^{(p^{r+1}-1)/(p^2-1)} = 1
\]

for all root \( r \) in \( \mathbb{F}_{p^k} \).

**III. Upper Bound on the Cross-Correlation Function**

Let \( k \) be an integer and \( n = 2m = 2 + 4k \), \( d = 3^n - 3^{m+2} + 3^m \). Suppose \( \mathbb{F}_{3^n} \) is a finite field with \( 3^n \) elements. Set \( \alpha \) be a primitive element of \( \mathbb{F}_{3^n} \). Let \( N = 3^n - 1 \) be the period of \( m \)-sequence in \( \mathbb{F}_{3^n} \). Then \( \gcd(N,d) = 3^{m+1} \). Set \( 0 \leq l < N/\gcd(N,d) = 4(3^m + 1) \). We consider the cross-correlation function \( C(\tau) \) between \( \tau \mathbb{R}^t(\alpha^t) \) and \( \tau \mathbb{R}^t(\alpha^{dt+l}) \) with time shift \( \tau \). Then \( C(\tau) \) is given as

\[
C(\tau) = \sum_{t=0}^{N-1} \omega^{\tau t (\alpha^t - \alpha^{dt+l})} = \sum_{t=0}^{N-1} \omega^{\tau t (\alpha^{-t} - \alpha^{-dt})} = \sum_{x \in \mathbb{F}_{3^n}} \omega^{\tau x (x-\gamma x^d)}
\]
where $\gamma \equiv \alpha^{d} r_{1} + 1$ and $\omega$ is a third primitive root of unity. Let $x = y^{3^{n-1}}$. Since $d(3^{n-1} - 1) = 3^{n/2} + 1 = 3^{n+1} \mod N$, we have

$$\text{tr}_{d}^{n}(x - \gamma x^{d}) = \text{tr}_{d}^{n}(y^{3^{n-1} - 1} - \gamma y^{3^{m+1}}).$$

Thus we have quadratic forms in $y$. Since $(3^{n-1} - 1, 3^{n} - 1) = 4$, we must consider $a_{i} \in C_{i}$, $0 \leq i \leq 3$, so that

$$4(1 + C(\tau)) = 4 \left( \sum_{x \in F_{3^{n}}} \omega \text{tr}_{1}^{n}(x - \gamma x^{d}) \right) = \sum_{i=0}^{3} \sum_{y \in F_{3^{n}}} \omega \text{tr}_{i}^{n}(a_{i} y^{3^{n-1} - 1} - \gamma a_{i} y^{3^{m+1}})$$

where $C_{i} = \{ \alpha^{4i+1} | 0 \leq t < \frac{3^{n}-1}{4} \}$. Here $g_{i}(y) = \text{tr}_{i}^{n}(a_{i} y^{3^{n-1} - 1} - \gamma a_{i} y^{3^{m+1}})$, $0 \leq i \leq 3$, are quadratic forms. To derive the upper bound of the absolute values of the cross-correlation, it is standard to obtain the rank of the quadratic forms and apply Lemma 1. By Lemma 3, investigating the rank of $g_{i}(y)$ can be done by counting the number of $z$ such that $g_{i}(y + z) - g_{i}(y) = 0$ for all $y \in F_{3^{n}}$. Simplifying the equation $g_{i}(y + z) - g_{i}(y) = 0$ gives us

$$\text{tr}_{i}^{n}(y(a_{i}^{3} z + a_{i} z^{3^{n-1}} - (\gamma a_{i}^{d})^{3^{n}} z^{3^{m}} - \gamma a_{i}^{d} z^{3^{m}}) + a_{i} z^{3^{n-1} + 1} - \gamma a_{i}^{d} z^{3^{m} + 1}) = 0.$$

To satisfy this equation for all $y$, we must have

$$a_{i}^{3} z^{3} + a_{i} z^{3^{n-1}} - (\gamma a_{i}^{d})^{3^{n}} z^{3^{m}} - \gamma a_{i}^{d} z^{3^{m}} = 0$$

and

$$\text{tr}_{i}^{n}(a_{i} z^{3^{n-1} + 1} - \gamma a_{i}^{d} z^{3^{m} + 1}) = 0.$$

Here we claim that the first equation is sufficient condition for the second. Indeed,

$$a_{i}^{3} z^{3} + a_{i} z^{3^{n-1}} - (\gamma a_{i}^{d})^{3^{n}} z^{3^{m}} - \gamma a_{i}^{d} z^{3^{m}} = 0
\iff a_{i}^{3} z^{3} + a_{i} z^{3^{n-1}} - (\gamma a_{i}^{d})^{3^{n}} z^{3^{m}} - \gamma a_{i}^{d} z^{3^{m}} = 0
\iff a_{i}^{3} z^{3} + a_{i} z^{3^{n-1}} - (\gamma a_{i}^{d})^{3^{n}} z^{3^{m}} - \gamma a_{i}^{d} z^{3^{m}} = 0
\iff \text{tr}_{i}^{n}(a_{i} z^{3^{n-1}} + 1 - \gamma a_{i}^{d} z^{3^{m}} + 1)
\iff \text{tr}_{i}^{n}(a_{i} z^{3^{n-1}} + 1 - \gamma a_{i}^{d} z^{3^{m}} + 1)
\iff 2\text{tr}_{i}^{n}(a_{i} z^{3^{n-1} + 1} - \gamma a_{i}^{d} z^{3^{m} + 1}) = 0
\iff 2\text{tr}_{i}^{n}(a_{i} z^{3^{n-1} + 1} - \gamma a_{i}^{d} z^{3^{m} + 1}) = 0.$$

Let $f_{i}(z) = a_{i}^{3} z^{3} + a_{i} z^{3^{n-1}} - (\gamma a_{i}^{d})^{3^{n}} z^{3^{m}} - \gamma a_{i}^{d} z^{3^{m}}$. By the discussion above, it is sufficient to count the number of roots of linearized polynomial $f_{i}(z)$. Now we prove that the number of roots of the linearized polynomial $f_{i}(z)$ is one of $1, 9,$ and $81$. Note that the linearized polynomial $f_{i}(z)$ has the degree $3^{n-1}$, which is not constant, but depends on $n$.

Lemma 7: The number of roots of the linearized polynomial $f_{i}(z)$, $i = 0, 1, 2$ or $3$, is one of $1, 9,$ and $81$.

Proof: We have the following equalities

$$a_{i}^{3} z^{3} + a_{i} z^{3^{n-1}} - (\gamma a_{i}^{d})^{3^{n}} z^{3^{m}} - \gamma a_{i}^{d} z^{3^{m}} = 0$$

$\Leftrightarrow a_{i}^{3} z^{3} + a_{i} z^{3^{n-1}} = ((\gamma a_{i}^{d})^{3^{n}} + \gamma a_{i}^{d}) z^{3^{m}}$.

Here we assume $z \neq 0$. By dividing the both sides by $z^{3^{m}}$, we obtain

$$a_{i}^{3} + a_{i} z^{3^{n-1} - 3^{m}} = ((\gamma a_{i}^{d})^{3} + \gamma a_{i}^{d}).$$

Let $X = z^{3^{n-1} - 1}$. Since $(3^{n-1} - 1, 3^{n} - 1) = 3^{2} - 1 = 8$, this transform is an 8-1 map. Define $B_{i} = (\gamma a_{i}^{d})^{3} + \gamma a_{i}^{d}$ and $Y = a_{i} X$. Then the equality becomes

$$a_{i}^{3} + a_{i} X^{3^{m}} = B_{i} \Leftrightarrow \frac{1}{Y^{3}} + a_{i}^{3^{m+1}} Y^{3^{m}} = B_{i}.$$

Set $A_{i} = a_{i}^{3^{m+1}}$. Note $A \in F_{3^{m}}$. Let $Y^{3} = x$. It is a one-to-one mapping since $(3^{n} - 1, 3)$ = 1. Thus,

$$\frac{1}{Y^{3}} + A_{i} Y^{3^{m}} = B_{i} \Leftrightarrow \frac{1}{x} + A_{i} x^{3^{m-1}} = B_{i} \Leftrightarrow 1 + A_{i} x^{3^{m-1} + 1} = B_{i} x.$$

Here we let $x = \frac{1}{B_{i}} y$. Then we have

$$1 + A_{i} \left( \frac{1}{B_{i}} y \right)^{3^{m-1} + 1} = B_{i} \frac{1}{B_{i}} y \Leftrightarrow 1 + \frac{A_{i}}{B_{i}^{3^{m-1} + 1}} y^{3^{m-1} + 1} = y.$$ (1)

Let $\frac{A_{i}}{B_{i}^{3^{m-1} + 1}} = \frac{1}{c_{i}}$. Then (1) becomes

$$1 + \frac{1}{c_{i}} y^{3^{m-1} + 1} \Leftrightarrow y^{3^{m-1} + 1} - c_{i} y + c_{i} = 0.$$ Then by Lemma 4, the number of solutions of $y^{3^{m-1} + 1} - c_{i} y + c_{i} = 0$ is one of $0, 1, 2, \text{ and } 3^{(m-1)n} + 1 = 3^{2} + 1 = 10$. Since the mapping is 8-1 map, the number of solutions is one among 0, 8, 16, and 80. Adding a zero root ($z = 0$), we have 1, 9, 17, and 81. Since the original equation is a linearized polynomial, 17 cannot be a number of root. Thus the linearized polynomial can have only 1, 9, and 81 roots.

Next we show that among the four linearized polynomials $f_{i}(z)$, $0 \leq i \leq 3$, at most one polynomial can have 81 roots.

Lemma 8: Among the four linearized polynomials $f_{i}(z)$, $0 \leq i \leq 3$, at most one polynomial can have 81 solutions. Or equivalently, among four polynomials $h_{i}(y) = y^{3^{n-1} + 1} - c_{i} y + c_{i}$, $0 \leq i \leq 3$, at most one polynomial can have 10 solutions.

Proof: Without loss of generality, we may assume that $a_{i} = \alpha^{i}$. By the previous lemma, we have the following relation

$$c_{i} = \frac{(\text{tr}_{m}(\gamma a_{i}^{d}))^{3^{n-1} + 1}}{a_{i}^{3^{m+1}}}, y = \frac{\text{tr}_{m}(\gamma a_{i}^{d})}{a_{i}^{3}} z^{3^{m-3}}.$$ (2)
Suppose \( \beta = \alpha^{3m+1} = \alpha^{3m+1} \) is a primitive element of the subfield \( \mathbb{F}_{3^m} \). Since \( a_i^{3m+1} = (\alpha^i)^{3m+1} = \beta^i \), for \( i = 0, 2 \), \( a_i^{3m+1} \) is a square in the subfield, and for \( i = 1, 3 \), \( a_i^{3m+1} \) is a nonsquare element of the subfield. The numerator \( (\text{tr}_n^m(\gamma a_i^3))^{3m+1} \) is always a square in the subfield \( \mathbb{F}_{3^m} \). Consequently, \( c_i \) is a square in the subfield if \( i = 0, 2 \), and a nonsquare if \( i = 1, 3 \). We claim that only \( f_0(z) \) can have 81 roots. Suppose \( f_1(z) \) has 81 roots. First assume that \( i = 0 \) or \( i = 2 \). By Corollary 6, we have

\[
\frac{y^{3m+1}}{c_i} = (\alpha^{8l}) \frac{y^{3m+1}}{c_i} = 1.
\]

Since \( c_i \) is a square in \( \mathbb{F}_{3^m} \), \( c_i = \beta^{2k} \) for some \( k \). Also note that \( \beta = \alpha^{4l} \) for some \( l \). Therefore we have

\[
\frac{y^{3m+1}}{c_i} = (\alpha^{8l}) \frac{y^{3m+1}}{c_i} = 1.
\]

Thus \( (y^{3m+1}) \frac{y^{3m+1}}{c_i} = 1 \). Since \( 3^m - 1 = 1 \) mod 4, we can substitute as \( y^{3m+1} = x^{4}k+2 \). Then we have

\[
\frac{y^{4}k+2}{c_i} = (\alpha^{8l}) \frac{y^{4}k+2}{c_i} = 1.
\]

Therefore \( y^{3m+1} = x^{4}k+1 = \alpha^{4l'} \) for some \( l' \). But since \( (\alpha^{3m+1}) = 1 \), we have \( y = \alpha^{4l} \). (2), \( yq_i = \text{tr}_m(\gamma a_i^3) = \text{tr}_m(\gamma a_i^3) = 3 \). Here all terms in the right hand side are in \( C_0 \). We already observed that \( y \in C_0 \). Therefore we must have \( a_i = x^{4}k+2 \). This means that \( c_i = \beta^{2k+1} = (\alpha^{4l})^{k+1} = \alpha^{8l+2} \). Note that \( l \) is odd since \( m \) is odd. Applying Corollary 6 again, we have (3), but for this case, it follows that

\[
\frac{y^{3m+1}}{c_i} = (\alpha^{8l}) \frac{y^{3m+1}}{c_i} = (-1)^{(2k+1)}l = -1.
\]

Therefore \( y^{3m+1} = c_i \). Since \( 3^{m+1} = 1 \) mod 4, we can substitute as \( y^{3m+1} = 4k+2 \) for some \( k \). Then we have

\[
\left(\frac{y^{4}k+2}{c_i}\right) \left(\frac{y^{3m+1}}{c_i}\right) = -1 \iff \left(\frac{y^{4}k+2}{c_i}\right) \left(\frac{y^{3m+1}}{c_i}\right) = \alpha^{3m+1}k'.
\]

where \( k' \) is some odd integer. Thus \( y \) must be a square in \( \mathbb{F}_{3^m} \).

Let \( y = \alpha^{2l} \) for some integer \( l' \). From (4), it follows that

\[
\alpha^{3m+1}l' = \alpha^{3m+1}k'.
\]

Therefore, \( l' \) is odd. Thus \( y \in C_2 \). From (2), we have \( a_i = C_2 \). This implies that \( c_i \) is in \( C_2 \), which contradicts \( i = 0 \) or \( i = 3 \). Therefore if \( f_i(z) \) has 81 roots, then \( i = 0 \).

It is well known that the number of roots of the linearized polynomial \( f_i(z) \) is equal to \( 3^{m-rank(g_i(y))} \). Therefore by what we have dicussed so far, each \( g_i(y) \) has a rank of \( n \), \( n - 2 \), or \( n - 4 \), and only one of \( g_i(y) \) can have the rank \( n - 4 \) for \( i = 0, 1, 2, 3 \). Thus we can enumerate 9 possible rank combinations of \( g_i(y) \), \( i = 0, 1, 2, 3 \), ignoring order as

\[
(n, n, n, n), \ (n, n, n, n - 2), \ (n, n, n, n - 4), \ (n, n, n - 2, n - 2), \ (n, n, n - 2, n - 4), \ (n, n - 2, n - 2, n - 2), \ (n, n - 2, n - 2, n - 4), \ (n, n - 2, n - 2, n - 4), \ (n, n - 2, n - 2, n - 4).
\]

For each of these rank combinations, we can derive the upper bound of the cross-correlation values using Lemma 2. We will check only for the last case, \( (n - 2, n - 2, n - 2, n - 4) \). Using Lemma 2, it follows that

\[
4(1 + C(\tau)) = \sum_{i=0}^{3} \sum_{y \in \mathbb{F}_{3^m}} \omega^{g_i(y)} \geq 
\]

\[
= \epsilon_0 3^{3} 3^{\frac{3}{2}} + \epsilon_1 3^{3} 3^{\frac{3}{2}} + \epsilon_2 3^{2} 3^{\frac{3}{2}} + \epsilon_3 3^{3} 3^{\frac{3}{2}}
\]

\[
= 3(\epsilon_0 + \epsilon_1 + \epsilon_2)3^3 + 3^2 \epsilon_3 3^m
\]

\[
\leq 18 \cdot 3^m
\]

where \( \epsilon_0, \epsilon_1, \epsilon_2, \epsilon_3 \), are determined to be 1 or -1 according to the rank and determinant of the quadratic forms. Thus in this case, the magnitude of the cross-correlation function \( C(\tau) \) is upper bounded by \( 4.5 \cdot 3^m + 1 \). It is easily checked that among all the rank combinations above, \( (n - 2, n - 2, n - 2, n - 4) \) yields the largest upper bound for \( C(\tau) \). Therefore, we have the following theorem.

**Theorem 9:** For an integer \( k \geq 0 \), \( n = 4k + 2 = 2m \), \( d = \frac{3^m - 3^{m+2}}{4} + 3^m \), and \( 0 \leq l < 4(3^m + 1) \), the magnitude of the cross-correlation function \( C(\tau) \) between \( \text{tr}_n^m(\alpha^l) \) and \( \text{tr}_n^m(\alpha^l) \) is upper bounded by

\[
|C(\tau)| \leq 4.5 \cdot 3^m + 1.
\]

\[
\square
\]

**IV. DISCUSSION**

First we consider an example. Suppose \( n = 4k + 2 = 2m = 6 \) and \( d = 203 \). For all \( l \) going through 0 to 4(3^m + 1) - 1 = 103, by computer search, the cross-correlation distribution between \( \text{tr}_n^m(\alpha^l) \) and \( \text{tr}_n^m(\alpha^l) \) is given as

\[
C(\tau) =
\]

\[
\begin{array}{c}
-1, \quad \text{34328 times} \\
-2, \quad \text{18095 times} \\
0, \quad \text{14973 times} \\
0, \quad \text{833 times} \\
0, \quad \text{1938 times} \\
-55, \quad \text{5016 times} \\
53, \quad \text{1869 times}.
\end{array}
\]

Note that the cross-correlation is 7-valued. The similar result is obtained for \( n = 10 \). Based on these, we propose the following conjecture on the cross-correlation distribution.

**Conjecture 10:** For an integer \( k \geq 0 \), \( n = 4k + 2 = 2m \), \( d = \frac{3^m - 3^{m+2}}{4} + 3^m \), and \( 0 \leq l < 4(3^m + 1) \), the cross-correlation function \( C(\tau) \) between \( \text{tr}_n^m(\alpha^l) \) and \( \text{tr}_n^m(\alpha^l) \) takes values in \( \{-1, -1 \pm 3^m, -1 \pm 3^{m+1}, 3^m\} \).
Therefore the magnitude of $C(\tau)$ is upper bounded by $3 \cdot 3^m + 1$.

The main difficulty of the problem originates from two factors. First, since there are more than two quadratic forms involved, we have to exclude more candidate values for the cross-correlation. In computer search, we found that every involved, we have to exclude more candidate values for the factors. First, since there are more than two quadratic forms

due to this is to set $g_i(y) = rg_j(y)$ for some nonsquare $r$ so that $\det(g_i) = r^k \det(g_j)$, where $k$ is a rank of $g_i$ and $g_j$. If $k$ is odd, we can conclude that $\epsilon_i = -\epsilon_j$ as we wish to show. But in our case, all ranks of quadratic forms are even. This is the second factor which makes the problem difficult.

V. Conclusion

In this paper, we investigate the upper bound for the crosscorrelation function between a ternary $m$-sequence of period $n = 4k + 2$ and its decimated sequence with the decimation $d = 2^{4k+2} - 2^{2k+1} + 2 + 3^{2k+1}$. It is shown that the cross-correlation is upper bounded by $4 \cdot 3^{n/2} + 1$. For the derivation, it is proved that $1, 9, 81$ are only possible number of solutions of linearized polynomials and only one among four linearized polynomials can have $81$ roots. A conjecture on the exact cross-correlation value is proposed as an open problem.
