Hereditary undecidability of some theories of finite structures.

Ross Willard

Abstract

Using a result of Gurevich and Lewis on the word problem for finite semigroups, we give short proofs that the following theories are hereditarily undecidable: (1) finite graphs of vertex-degree at most 3; (2) finite nonvoid sets with two distinguished permutations; (3) finite-dimensional vector spaces over a finite field with two distinguished endomorphisms.

1 Introduction

All theories in this note are first-order, consistent but not necessarily complete, and have finite languages. Let $T_1$ and $T_2$ be theories in possibly different languages. We write $T_1 \leq T_2$ to mean there exists $\mathcal{K}_1 \subseteq \text{Mod}(T_1)$ such that $\text{Th}(\mathcal{K}_1) = T_1$ and the members of $\mathcal{K}_1$ are uniformly interpretable by formulas in the models of $T_2$, as this is defined in [2, 12]. (This variant of Rabin’s method [15] allows the use of parameters and definable factor relations.) Also let $T_1 \equiv T_2$ mean $T_1 \leq T_2 \leq T_1$. $\leq$ induces a partial ordering of the $\equiv$-classes, roughly measuring the complexity of the models of a theory.

This ordering is compatible with some of the properties of interest to model theorists: e.g., the classes of theories all of whose models are stable, superstable, or $\aleph_0$-categorical form down-sets with respect to $\leq$. The ordering is

\[1991 \textit{Mathematics Subject Classification}: \text{Primary 03D35; Secondary 03C13.} \]

\[2 \textit{Key words and phrases}: \text{undecidable theory, interpretable, finite graphs, finite modules, word problem} \]

\[3 \text{This research was supported by the NSERC of Canada.} \]
known to have a maximum element, represented by the theory of the class $G$ of graphs, but otherwise has not been explored.

Recent results on the decidability of theories of locally finite varieties are perhaps better stated in terms of $\leq$. For example, the beautiful theorem of McKenzie and Valeriote [12] can be viewed as giving a transparent structural characterization of those finitely generated varieties $\mathcal{V}$ in a finite language satisfying $\text{Th}(\mathcal{V}) \neq \text{Th}(G)$, and reducing the corresponding problem for locally finite varieties to the special case of discriminator varieties. Another example is the ongoing classification of those sufficiently recursive rings $R$ for which the class $\mathcal{M}_R$ of $R$-modules has a decidable theory. This project, at least when restricted to finite rings, seems (see e.g. [1, 13, 14]) to amount to classifying $R$ according to whether $\text{Th}(\mathcal{M}_K^{2\text{aut}}) \not\leq \text{Th}(\mathcal{M}_R)$ for all finite fields $K$. (Here $\mathcal{M}_K^{2\text{aut}}$ is the class of $K$-vector spaces with 2 distinguished automorphisms.)

Let $T_1$ be either $\text{Th}(G)$ or $\text{Th}(\mathcal{M}_K^{2\text{aut}})$ for some finite field $K$. $T_1$ is undecidable (by [16] and [1, 13] respectively), and also finitely axiomatizable. Thus

$$T_1 \leq T_2 \implies T_2 \text{ is undecidable.}$$

In general, any theory $T_1$ satisfying (1) is said to be hereditarily undecidable. The two examples in the previous paragraphs can also be seen as (partial) affirmations of the following thesis: if $\mathcal{V}$ is a locally finite variety (in a finite language) such that $\text{Th}(\mathcal{V})$ is not hereditarily undecidable, then $\mathcal{V}$ has good structure.

Attention among universal algebraists is now turning to the search for structure in arbitrary pseudovarieties (classes of finite algebras closed under quotients, subalgebras, and products) whose theories are not hereditarily undecidable [7, 8, 9, 10, 19]. Since $\text{Th}(G) \not\leq \text{Th}(\mathcal{V})$ and $\text{Th}(\mathcal{M}_K^{2\text{aut}}) \not\leq \text{Th}(\mathcal{V})$ if $\mathcal{V}$ is a class of finite structures, hereditary undecidability of a pseudovariety $\mathcal{V}$ lacking structure must be established by other means. In all results currently known to us this is accomplished by showing $\text{Th}(G_{\text{fin}}) \leq \text{Th}(\mathcal{V})$, where $G_{\text{fin}}$ denotes the class of all finite graphs (whose theory is hereditarily undecidable by [11]).

Our purpose in this note is to give a few more tools for proving the hereditary undecidability of pseudovarieties. Let $k-G$ denote the class of all graphs of vertex-degree at most $k$; let $n-P$ denote the class of all nonvoid
sets with \( n \) distinguished permutations; for a finite field \( K \) let \( \mathcal{M}_K^{2\text{end}} \) be the class of all \( K \)-vector spaces with two distinguished endomorphisms; and for a class \( \mathcal{K} \) let \( \mathcal{K}_{\text{fin}} \) denote the class of finite members of \( \mathcal{K} \). We prove:

1. For all \( k \geq 3 \) and \( n \geq 2 \), \( \text{Th}(k-G) \equiv \text{Th}(3-G) \equiv \text{Th}(n-P) \equiv \text{Th}(2-P) \) and \( \text{Th}(k-G_{\text{fin}}) \equiv \text{Th}(3-G_{\text{fin}}) \equiv \text{Th}(n-P_{\text{fin}}) \equiv \text{Th}(2-P_{\text{fin}}) \);  
2. Each theory in the previous item is hereditarily undecidable;  
3. For each finite field \( K \), \( \text{Th}((\mathcal{M}_K^{2\text{end}})_{\text{fin}}) \) is hereditarily undecidable. 

Item (1) implies that every graph of bounded vertex-degree is superstable, hence \( \text{Th}(G_{\text{fin}}) \not\leq \text{Th}(3-G) \).

Item (3) together with known results prove the hereditary undecidability of \( \text{Th}((\mathcal{M}_R^{2\text{end}})_{\text{fin}}) \) for many finite rings \( R \). Items (2) and (3) are proved via a result of Gurevich and Lewis on the word problem for finite semigroups.

2 Results

For \( n \geq 2 \) let \( L_n \) be the language consisting of the \( n \) binary relation symbols \( R_0, \ldots, R_{n-1} \). Let \( n-I \) be the class of all \( L_n \)-structures in which each \( R_i \) is the graph of a partial injective function. If \( \langle A; R_0, \ldots, R_{n-1} \rangle \in n-I \) then we let \( \text{dom}(R_i) \) and \( \text{ran}(R_i) \) denote the projections of \( R_i \) onto its first and second coordinates, and we write \( R_i(a) = b \) to mean \( (a, b) \in R_i \).

**THEOREM 2.1** For all \( k \geq 3 \) and \( n \geq 2 \),

1. \( \text{Th}(k-G) \equiv \text{Th}(3-G) \equiv \text{Th}(n-I) \equiv \text{Th}(2-I) \equiv \text{Th}(n-P) \equiv \text{Th}(2-P) \);
2. Same as the previous item but with each class replaced by its finite members.

**Proof.** Clearly \( \text{Th}(3-G) \leq \text{Th}(k-G) \) and \( \text{Th}(n-P) \leq \text{Th}(n-I) \), and similarly for the corresponding classes of finite structures. Therefore to prove item 1 it will suffice to prove \( \text{Th}(k-G) \leq \text{Th}((k+1)-I) \), \( \text{Th}(n-I) \leq \text{Th}(2-P) \), and \( \text{Th}(2-I) \leq \text{Th}(3-G) \); and item 2 will follow from the corresponding claims for the finite structures.

We first show \( \text{Th}(k-G) \leq \text{Th}((k+1)-I) \). Let \( \langle V, E \rangle \) be a graph of vertex-degree at most \( k \). By Vizing’s theorem (which is true for infinite as well as finite graphs), the edges of \( \langle V, E \rangle \) can be \((k+1)\)-colored. Choose such a coloring \( \chi : E \to \{0, 1, \ldots, k\} \). Fix a well-ordering \( < \) of \( V \). Now we construct a member of \((k+1)-I\) with universe \( V \) by defining \( R_i(v) = w \) if
and only if \( v < w, \{v, w\} \in E, \) and \( \chi(\{v, w\}) = i. \) \( \langle V, E \rangle \) can be recovered from \( \langle V; R_0, \ldots, R_k \rangle \) by means of the following formulas:

\[
\begin{align*}
V(x) & : x = x \\
E(x, y) & : \bigvee_{i=0}^{k} [R_i(x) = y \lor R_i(y) = x].
\end{align*}
\]

This proves both \( \text{Th}(k, G) \leq \text{Th}((k+1) - I) \) and \( \text{Th}(k, G_{\text{fin}}) \leq \text{Th}((k+1) - I_{\text{fin}}). \)

Next we show \( \text{Th}(2 - I) \leq \text{Th}(3 - G). \) Let \( A = \langle A; R_0, R_1 \rangle \) be an arbitrary member of \( 2 - I. \) We shall build a graph \( \langle V, E \rangle \) of vertex-degree at most three in which \( A \) can be defined. First let \( \hat{A} = A \times \{0,1\} \times \{in, out\}, \)

\( \hat{R}_0 = R_0 \times \{1, 2, 3, t\} \) and \( \hat{R}_1 = R_1 \times \{1', 2', 3', 4', t'\}. \) Put \( V = \hat{A} \cup \hat{R}_0 \cup \hat{R}_1. \) For each \( a \in A \) and \( e = (b, d) \in R_0 \) let \( \langle V_a, E_a \rangle \) and \( \langle V_e^0, E_e^0 \rangle \) be the graphs pictured below.

\[
\langle V_a, E_a \rangle \text{ where } a \in A \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \ quad...
$R_0(\bar{x}, \bar{y}) : A(\bar{x}) \land A(\bar{y}) \land \exists z_0 \exists z_1 \cdots \exists z_5 (\{|\{z_0, \ldots, z_5\}| = 6 \land z_0 E z_1 E z_2 E z_3 E z_4 E z_5 \land z_3 E z_5 \land \{z_0, z_1\} \cap \{x_1, \ldots, x_4\} = \{z_0\} \land \{z_3, z_5\} \cap \{y_1, \ldots, y_4\} = \{z_5\})$

and let $R_1(\bar{x}, \bar{y})$ be defined in the obvious analogous way. Then $\theta := Eq^{(V, E)}$ is a factor relation of the $L_2$-structure $A' := \langle A^{(V, E)}; R_0^{(V, E)}, R_1^{(V, E)} \rangle$, and $A'/\theta \cong A$. The above formulas did not depend in any way on $A$, which proves $Th(2-I) \leq Th(3-G)$. Since in this construction $\langle V, E \rangle$ is finite if $A$ is, we also get $Th(2-I_{fin}) \leq Th(3-G_{fin})$.

Finally we show $Th(n-I) \leq Th(2-P)$. Let $A = \langle A; R_0, \ldots, R_{n-1} \rangle \in n-I$ be given. Our goal is to construct an algebra $B = \langle B; f, g \rangle$ where $f$ and $g$ are permutations of $B$ and in which $A$ may be defined. For each $a \in A$ let $C_a$ be the set $\{a\} \times \{0, 1, \ldots, n-1\} \times \{in, out\}$ with $f$ and $g$ partially defined as follows:

\[
\begin{align*}
  f((a, i, in)) &= (a, i, out) \\
  g((a, i, in)) &= \begin{cases} (a, i + 1, in) & \text{if } i < n - 1 \\ (a, n - 1, out) & \text{if } i = n - 1 \end{cases} \\
  g((a, i, out)) &= \begin{cases} (a, i - 1, out) & \text{if } i > 0 \\ (a, 0, in) & \text{if } i = 0. \end{cases}
\end{align*}
\]

(The reader is advised to draw a picture.) Note that $C_a$ is rigid as a partial bi-unary algebra. Let $A$ be the union of all the $C_a$’s.

Next for $i < n$ let $\hat{R}_i = R_i \times \{i\}$ and put $B_0 = \hat{A} \cup \hat{R}_0 \cup \cdots \cup \hat{R}_{n-1}$. Extend $f$ and $g$ by defining, for each $i < n$ and $e = (b, d) \in R_i$,

\[
\begin{align*}
  f((b, i, out)) &= (e, i) \\
  f((e, i)) &= (d, i, in) \\
  g((e, i)) &= (e, i).
\end{align*}
\]

Note that $g$ is a permutation of $B_0$ while $f$, though injective, is only partially defined. Thus we have not yet finished our construction of $B$. Nonetheless it may be helpful at this point to say what our formulas will be. Let $A(x_0, \ldots, x_{2n-1})$ be the conjunction of $\wedge_{i < j < 2n} x_i \neq x_j$ and

\[
\wedge_{i < n} f(x_i) = x_{n+i} \land \wedge_{i < n} f(x_{n+i}) \notin \{x_0, \ldots, x_{2n-1}\} \land
\]
\[
\bigwedge_{i<n-1} g(x_i) = x_{i+1} \land g(x_{n-1}) = x_{2n-1} \land \\
\bigwedge_{i<n-1} g(x_{n+i+1}) = x_{n+i} \land g(x_n) = x_0 
\]

while for each \(i < n\) let \(R_{i}(\bar{x}, \bar{y})\) be the formula

\[
A(\bar{x}) \land A(\bar{y}) \land \exists z \left[ g(z) = z \land f(x_{n+i}) = z \land f(z) = y_i \right].
\]

Now we complete the construction of \(B\). For each \(i < n\) and \(a \in A \setminus \text{dom}(R_i)\) choose an infinite set \(S^i_a\) and designated element \(p^i_a\), together with unary functions \(f = f^i_a\) and \(g = g^i_a\) on \(S^i_a\) satisfying: (i) \(g\) is a bijection; (ii) for all \(x \in S^i_a\) and \(m < n < \omega\), \(g^m(x) \neq g^n(x)\); (iii) \(f\) is total and injective; (iv) \(\text{ran}(f) = S^i_a \setminus \{p^i_a\}\). Construct the union of \(B_0\) and all of the \(S^i_a\)'s (making sure the underlying sets are pairwise disjoint), and further extend \(f\) by defining \(f((a,i,\text{out})) = p^i_a\) if \(a \in A \setminus \text{ran}(R_i)\). Then perform the dual construction for each \(a \in A \setminus \text{ran}(R_i)\). The resulting structure, which we call \(B\), is a member of \(2\cdot\mathcal{P}\) and satisfies \(<A^B; R^B_0, \ldots, R^B_{n-1}> \cong A\). This proves \(\text{Th}(n\cdot\mathcal{I}) \leq \text{Th}(2\cdot\mathcal{P})\).

Unfortunately \(B\) is infinite even if \(A\) is finite (unless every \(R_i\) happens to be a permutation). Therefore a different construction is needed to prove \(\text{Th}(n\cdot\mathcal{I}_{\text{fin}}) \leq \text{Th}(2\cdot\mathcal{P}_{\text{fin}})\). Suppose \(A \in n\cdot\mathcal{I}_{\text{fin}}\). Let \(B_0\) be defined as before. Fix \(i < n\). Because \(R_i\) is a partial injective function, and by finiteness, we can pick a bijection \(\phi_i : A \setminus \text{dom}(R_i) \to A \setminus \text{ran}(R_i)\). For each \(a \in \text{dom}(\phi_i)\) add two new points \((a,i,1)\) and \((a,i,2)\), and define \(g((a,i,j)) = (a,i,j)\) \((j = 1,2)\) and \(f((a,i,\text{out})) = (a,i,1), f((a,i,1)) = (a,i,2)\) and \(f((a,i,2)) = (\phi_i(a),i,\text{in})\). Let this be done for all \(i < n\), and let \(B\) be the resulting structure. Again \(B \in 2\cdot\mathcal{P}\) and \(<A^B; R^B_0, \ldots, R^B_{n-1}> \cong A\), and this time \(B\) is finite.

Next we describe a result of Gurevich and Lewis [6] which we shall need. A cancellation semigroup with zero and identity is a semigroup with zero and identity which satisfies

\[
\text{If } xy = xz \neq 0 \text{ or } yx = zx \neq 0, \text{ then } y = z.
\]

Let \(A\) be the set of quasi-identities valid in all semigroups, and let \(\neg FC\) be the set of quasi-identities refuted in some finite cancellation semigroup with zero and identity. Gurevich and Lewis proved that \(A\) and \(\neg FC\) are
recursively inseparable. To prove this, they adopted a specialized version of Turing machines, which among other things requires at least two halting states, one of which is $q_1$. Then they described an effective procedure which to each such Turing machine $M$ with associated tape symbol set $T = T_0 \cup \{a_0\}$ ($a_0$ being the blank symbol) assigns a finite semigroup presentation $\langle \Delta; E \rangle$ having several nice properties. In the discussion which follows, we shall let $\langle \Delta; E \rangle$ be exactly as described in [6], except that we delete the symbol $A_0$ from $\Delta$, and we delete the ‘initialization rule’ $A_0 = \uparrow q_0^0\uparrow$ from $E$ (so that item 5 below will be true).

We adopt the following notation: $\Delta^*$ is the semigroup of all words over the alphabet $\Delta$; $\sim_E$ is the congruence of $\Delta^*$ generated by $E$. (Thus $\Delta^*/\sim_E$ is the semigroup presented by $\langle \Delta; E \rangle$.) The useful properties of $\langle \Delta; E \rangle$ are:

1. $T \cup \{\uparrow\} \subseteq \Delta$. ($\uparrow$ is an end-of-tape marker.)

2. $\Delta$ contains a set $Q'$ of symbols, disjoint from $T \cup \{}$, one member being $q_0^0$. ($Q'$ is in two-to-one correspondence with the set of states of $M$.)

3. $\Delta$ contains a symbol 0 such that $x0 \sim_E 0x \sim_E 0$ for all $x \in \Delta^*$.

4. For all $w \in T_0^*$, $M$ on input $w$ halts in state $q_1$ if and only if $\uparrow q_0^0w\uparrow \sim_E 0$.

The above items are typical of encodings of Turing machines in semigroup word problems. Next come the special properties. Let

$$Y = \{x \in \Delta^* : x \sim_E 0 \text{ and } x \text{ has at most one occurrence of a symbol from } Q'\}.$$ 

5. $Y$ is closed under $\sim_E$.

6. For all $w \in T_0^*$, $M$ on input $w$ halts in a state different from $q_1$ if and only if $\uparrow q_0^0w\uparrow \in Y$ and the $\sim_E$-class containing $\uparrow q_0^0w\uparrow$ is finite.

7. For all $x, y, z \in \Delta^*$, if $xy, xz \in Y$ and $xy \sim_E xz$, then $y \sim_E z$; and if $yx, zx \in Y$ and $yx \sim_E zx$, then $y \sim_E z$. 

7
(In their paper, Gurevich and Lewis prove items 4 and 6 only when \( w \) is the empty word, but their proofs work for all \( w \). Item 5 is an immediate consequence of the definition of \( E \), while item 7 is essentially proved in their analysis of \( G \) on page 190. The reader should note the following misprint in [6]: the transition symbols \( \sigma_m \) must be indexed by \( m \in (Q' \times T) \cup \{0\} \), and the transition rules must be modified by requiring that \( m = (q_i^e, a_k) \).

For each \( n < \omega \) let \( Q_n \) denote the set of all quasi-identities in the variables \( v_0, \ldots, v_{n-1} \) (in the language of semigroups). Recall that \( A \) is the set of quasi-identities valid in all semigroups, while \( \neg FC \) is the set of quasi-identities refuted in some finite cancellation semigroup with zero and identity. Also let \( \neg F \) be the set of quasi-identities refuted in some finite semigroup. A slight modification of the argument in [6] yields:

**Lemma 2.2**  
1. There exists \( n < \omega \) such that \( A \cap Q_n \) and \( \neg FC \cap Q_n \) are recursively inseparable.

2. \( A \cap Q_2 \) and \( \neg F \cap Q_2 \) are recursively inseparable.

**Proof.** Begin by choosing a finite alphabet \( T_0 \) and two recursively enumerable subsets \( U_1, U_2 \) of \( T_0^* \) such that \( U_1 \) and \( U_2 \) are recursively inseparable. By standard methods it can be shown that there is a Turing machine \( M \) of the kind used by Gurevich and Lewis, having exactly two halting states \( q_1, q_2 \), and such that for all \( w \in T_0^* \), \( M \) on input \( w \) halts in state \( q_i \) if and only if \( w \in U_i \) (\( i = 1, 2 \)). Obtain \( \langle \Delta; E \rangle \) for \( M \) as described above, and let \( n = |\Delta| \). We may assume with no loss of generality that \( \{v_0, \ldots, v_{n-1}\} = \Delta \). Let \( \phi \) be the conjunction of the relations (equations) in \( E \). For each \( w \in T_0^* \) let \( \phi_w \in Q_n \) be the quasi-identity \( \phi \rightarrow (\uparrow q_0^0 w \uparrow = 0) \). We claim that (i) \( w \in U_1 \) if and only if \( \phi_w \in A \), and (ii) if \( w \in U_2 \) then \( \phi_w \in \neg FC \). (i) follows from item 4 above. (ii) is proved as in [6]: if \( w \in U_2 \) then let \( W \) be the \( \sim_E \)-class containing \( \uparrow q_0^0 w \uparrow \) and let \( X \) be the set of all subwords (including the empty word) of members of \( W \). \( X \) is a finite subset of \( Y \) and is closed under \( \sim_E \). Let \( X^c = \Delta^* \setminus X \); then \( X^c/\sim_E \) is an ideal of the semigroup \( \Delta^*/\sim_E \). Thus \( X/\sim_E \cup \{0\} \) with the product \( (x/\sim_E)(y/\sim_E) \) defined to be \( (xy)/\sim_E \) if \( xy \in X \), and 0 otherwise, is a finite semigroup with zero and identity which refutes \( \phi_w \); moreover, it satisfies the cancellation law by item 7 above. This proves (ii). Since the map \( w \mapsto \phi_w \) is effective and sends \( U_1 \) into \( A \cap Q_n \) and \( U_2 \) into \( \neg FC \cap Q_n \), it follows that \( A \cap Q_n \) and \( \neg FC \cap Q_n \) are recursively inseparable.
To prove the second item, choose a two-element alphabet \( \{a, b\} \) and let 
\[ h : \Delta^* \to \{a, b\}^* \]
be the injective homomorphism defined by \( h(v_i) = ba^{i+1}b \). 
Let \( \{\{a, b\}; hE\} \) be the semigroup presentation obtained by replacing each 
\[ x = y \in E \] by \( h(x) = h(y) \). Clearly if \( x \in \Delta^* \) and \( y' \in \{a, b\}^* \), then \( h(x)^{hE} y' \)
if and only if \( y' = h(y) \) for some \( y \in \Delta^* \) such that \( x \sim y \). Thus if \( w \in T_0^* \)
then \( M \) on input \( w \) halts in state \( q_1 \) if and only if \( h(q_0^0w^\uparrow)^{hE} h(0) \), while \( M \)
on input \( w \) halts in state \( q_2 \) if and only if \( h(q_0^0w^\uparrow) \in h(Y) \) and the \( hE \)-class
containing \( h(q_0^0w^\uparrow) \) is finite. In the latter case, if \( X' \) is the set of all subwords
of members of the \( hE \)-class containing \( h(q_0^0w^\uparrow) \), then \( X'/^{hE} \cup \{0\} \) with the
obvious multiplication is a finite semigroup satisfying the relations in \( hE \) and
refuting \( h(q_0^0w^\uparrow)^{hE} h(0) \). The reduction to quasi-identities in the previous
paragraph shows that \( A \cap Q_2 \) and \( \neg F \cap Q_2 \) are recursively inseparable. 

**THEOREM 2.3**

1. \( \text{Th}(3\mathcal{G}_{\text{fin}}) \) and \( \text{Th}(2\mathcal{P}_{\text{fin}}) \) are hereditarily undecidable.

2. For each finite field \( K \), \( \text{Th}((\mathcal{M}_K^{\text{end}})_{\text{fin}}) \) is hereditarily undecidable.

**Proof.** Let \( n \) witness the claim in Lemma 2.2.1. Recall that \( n\mathcal{I} \)
the class of structures \( \langle U; R_0, \ldots, R_{n-1} \rangle \) where each \( R_i \) is the graph of a
partial injective function on \( U \). Let \( n\mathcal{C} \) be the class of algebras \( \langle U; f_0, \ldots, f_{n-1}; 0 \rangle \)
where \( 0 \) is a constant and each \( f_i \) is a unary operation satisfying the axiom
\[ f_i(0) = 0 \land \forall x \forall y (f_i(x) = f_i(y) \neq 0 \to x = y). \]

Clearly \( \text{Th}(n\mathcal{C}_{\text{fin}}) \equiv \text{Th}(n\mathcal{I}_{\text{fin}}) \). Thus by Theorem 2.1 it suffices to prove
that \( \text{Th}(n\mathcal{C}_{\text{fin}}) \) is hereditarily undecidable. For each word \( \sigma = v_{i_1} \cdots v_{i_k} \)
in the variables \( v_0, \ldots, v_{n-1} \) let \( \hat{\sigma}(x) \) be the term \( f_{i_1} \cdots f_{i_k}(x) \). If \( \psi \in H_n \) is
\[ (\sigma_1 = \tau_1 \land \cdots \land \sigma_m = \tau_m) \to \sigma_0 = \tau_0 \]
then let \( \hat{\psi} \) be the sentence in the language of \( n\mathcal{C} \) obtained by replacing each
\( \sigma_i = \tau_i \) with \( \forall x [\hat{\sigma}(x) = \hat{\tau}(x)] \). Clearly \( \psi \) is true of all semigroups if and
only if \( \models \hat{\psi} \). On the other hand, suppose \( S \) is a finite cancellation semigroup
with zero and identity which refutes \( \psi \); pick \( a_0, \ldots, a_{n-1} \in S \) witnessing this.
For each \( i < n \) define \( f_i(x) = a_i x \), and define \( S = \langle S; f_0, \ldots, f_{n-1}; 0 \rangle \).
Then \( S \in n\mathcal{C}_{\text{fin}} \). As \( S \) has an identity it follows that \( S \models \sigma_i(a) = \tau_i(a) \) if and only
if $S \models \forall x[\hat{\sigma}_i(x) = \hat{\tau}_i(x)];$ hence $S$ refutes $\hat{\psi}$. These remarks together with Lemma 2.2.1 prove that $\text{Th}(n\cdot \mathcal{C}_\text{fin})$ is hereditarily undecidable.

2. Since every (finite) semigroup can be embedded in the semigroup of all endomorphisms of a (finite-dimensional) $K$-vector space, the above argument can essentially be repeated (using Lemma 2.2.2 this time) to prove hereditary undecidability of $\text{Th}((\mathcal{M}_K^{2\cdot \text{end}})_{\text{fin}})$.

Here are some comments regarding Theorem 2.3. (i) It is possible that part 1 of the theorem is folklore; if so, then we hope that our presentation of it is sufficiently novel to warrant publication. (ii) In particular, Garfunkel and Shank [5] have claimed (correctly) that the class of finite planar cubic graphs has a hereditarily undecidable theory; however the proof remains unpublished (cf. [18]). (iii) Part 2 of the theorem together with results in the literature allow one to deduce the hereditary undecidability of $\text{Th}((\mathcal{M}_R^{2\cdot \text{end}})_{\text{fin}})$ for many finite rings $R$. For example, let $p$ be a prime and put $R = \mathbb{Z}_p[x : x^2 = 0]$. Baur [1] showed how to interpret $\mathcal{M}_p^{2\cdot \text{end}}$ in $\mathcal{M}_R$; the same argument interprets $\mathcal{M}_p^{2\cdot \text{end}}$ in $\mathcal{M}_R$.

The hereditary undecidability of both $\text{Th}(\mathcal{M}_K^{2\cdot \text{aut}})$ and $\text{Th}((\mathcal{M}_K^{2\cdot \text{end}})_{\text{fin}})$ suggests an obvious problem.

**Problem 1:** Is $\text{Th}((\mathcal{M}_K^{2\cdot \text{aut}})_{\text{fin}})$ hereditarily undecidable, if $K$ is a finite field?

The answer should be yes, but the result of Gurevich and Lewis does not seem to be strong enough to prove it. What is apparently needed is the recursive inseparability of the sets of (i) open formulas in 2 variables (in the language $\{\cdot, -, 1\}$) which are valid in all groups, and (ii) open formulas in 2 variables which are refuted in some finite group. The best result in this direction is due to Slobodskoi [17]: there exists $n < \omega$ such that the sets of (i) open formulas in $n$ variables valid in all periodic groups, and (ii) open formulas in $n$ variables refuted in some finite group, are recursively inseparable. Slobodskoi’s result can be used to deduce the undecidability (though not the hereditary undecidability) of $\text{Th}((\mathcal{M}_K^{n\cdot \text{aut}})_{\text{fin}})$ for sufficiently large $n$.

Here is another problem, this time concerning discriminator varieties. Recall that a discriminator variety is any variety of the form $\text{HSP}(\mathcal{K})$ where $\mathcal{K}$ is a class of algebras satisfying

$$\forall x\forall y\exists z[(t(x, x, z) = z) \& (x \neq y \rightarrow t(x, y, z) = x)]$$
for some term $t(x, y, z)$ in the language of $K$. We have conjectured that if $V$ is a locally finite discriminator variety in a finite language, then $\text{Th}(V)$ is undecidable if and only if $\text{Th}(G) \equiv \text{Th}(V)$. However the corresponding conjecture for $V_{\text{fin}}$ may be false. Let $K$ be the class of all finite algebras $\langle A; b, t \rangle$ where $t$ is the ternary discriminator function on $A$ (i.e., $t(x, y, z) = x$ if $x \neq y$, $t(x, x, z) = z$) and $b$ is a binary operation satisfying the axiom

$$\forall x \forall y [b(x, y) \in \{x, y\} \land (b(x, y) = x \leftrightarrow b(y, x) = y)] \land$$

$$\forall x \forall y_1 \forall y_2 \forall y_3 \forall y_4 [(b(x, y_1) = b(x, y_2) = b(x, y_3) = b(x, y_4) = x) \rightarrow$$

$$|\{x, y_1, y_2, y_3, y_4\}| < 5].$$

Let $V = \text{HSP}(K)$. $V$ is locally finite. Since $K$ coincides with the class of finite models of its universal theory, $V_{\text{fin}}$ is simply the class of finite direct products of members of $K$ (see [4, Theorem IV.9.4]). The reader should see that $K$ is bi-interpretable with $3G_{\text{fin}}$, so $\text{Th}(3G_{\text{fin}}) \leq \text{Th}(V_{\text{fin}})$. (It can also be shown by the methods in [3] or [20] that $\text{Th}(G) \equiv \text{Th}(V)$.)

**Problem 2:** Is it true that $\text{Th}(G_{\text{fin}}) \not\leq \text{Th}(V_{\text{fin}})$?
