

NUMERICAL APPROXIMATION OF FRACTIONAL POWERS OF ELLIPTIC OPERATORS

BEIPING DUAN, RAYTCHO D. LAZAROV, AND JOSEPH E. PASCIAK

ABSTRACT. In this paper, we develop and study algorithms for approximately solving the linear algebraic systems: $\mathcal{A}_h^\alpha u_h = f_h$, $0 < \alpha < 1$, for $u_h, f_h \in V_h$ with V_h a finite element approximation space. Such problems arise in finite element or finite difference approximations of the problem $\mathcal{A}^\alpha u = f$ with \mathcal{A} , for example, coming from a second order elliptic operator with homogeneous boundary conditions. The algorithms are motivated by the method of Vabishchevich [23] that relates the algebraic problem to a solution of a time-dependent initial value problem on the interval $[0, 1]$. Here we develop and study two time stepping schemes based on diagonal Padé approximation to $(1 + x)^{-\alpha}$. The first one uses geometrically graded meshes in order to compensate for the singular behavior of the solution for t close to 0. The second algorithm uses uniform time stepping but requires smoothness of the data f_h in discrete norms. For both methods, we estimate the error in terms of the number of time steps, with the regularity of f_h playing a major role for the second method. Finally, we present numerical experiments for \mathcal{A}_h coming from the finite element approximations of second order elliptic boundary value problems in one and two spatial dimensions.

1. INTRODUCTION

1.1. Motivation and problem formulation. Nonlocal operators arise in a wide variety of mathematical models such as modes of long-range interaction in elastic deformations [21], nonlocal electromagnetic fluid flows [18], image processing [8, 20] and many more. A recent discussion about the properties of such models and their applications to chemistry, geosciences, and engineering can be found in [13, 19].

The nonlocal operators considered in this paper involve fractional powers of operators \mathcal{A} associated with second order elliptic equations in bounded domains with homogeneous Dirichlet boundary conditions. The fractional power of \mathcal{A} is defined through the Dunford-Taylor integral, [10, 17], which is equivalent to the definition by the spectrum of \mathcal{A} . For a detailed discussion about this setting and other possible ways to define fractional powers of the Laplacian (and more general elliptic operators) we refer to [4, 14, 16]. We focus on issue of solving the corresponding algebraic system that arises in approximating such operators by the finite element method, e.g. [4, 5, 15].

We begin with the definition of the fractional power of a second order elliptic operator in a bounded domain $\Omega \subset \mathbb{R}^d$, $d = 1, 2, \dots$ with a Lipschitz continuous

Key words and phrases. fractional powers of elliptic operators, finite element approximation, Padé approximation, solution methods for equations involving powers of SPD matrices.

boundary. On $V \times V$, with $V = H_0^1(\Omega)$, we consider the bilinear form:

$$(1.1) \quad A(w, \phi) = \int_{\Omega} \left(a(x) \nabla w \cdot \nabla \phi + q(x) w \phi \right) dx,$$

and assume that the coefficients are such that the bilinear form is coercive and bounded on V . Further, we define $\mathcal{T} : L^2(\Omega) \rightarrow V$, where $\mathcal{T}v = w \in V$ is the unique solution to

$$(1.2) \quad A(w, \phi) = (v, \phi), \quad \phi \in V.$$

Here (\cdot, \cdot) denotes the $L^2(\Omega)$ -inner product.

Following [10], we define an unbounded operator \mathcal{A} with domain of definition $D(\mathcal{A})$ being the image of \mathcal{T} on $L^2(\Omega)$ and set $\mathcal{A}u = \mathcal{T}^{-1}u$ for $u \in D(\mathcal{A})$. This is well defined as \mathcal{T} is injective on $L^2(\Omega)$. Negative fractional powers can be defined by Dunford-Taylor integrals, i.e., for $\alpha > 0$ and $v \in L^2(\Omega)$,

$$\mathcal{A}^{-\alpha}v = \frac{1}{2\pi i} \int_{\mathcal{C}} z^{-\alpha} R_z(\mathcal{A})v dz$$

where $R_z(\mathcal{A}) = (\mathcal{A} - z\mathcal{I})^{-1}$ is the resolvent operator and \mathcal{C} is an appropriate contour in the complex plane (see, e.g., [17]).

Equivalently, fractional powers for the above example can be defined by eigenvector expansions. As \mathcal{T} is a compact, symmetric and positive definite operator on $L^2(\Omega)$, its eigenpairs $\{\psi_j, \mu_j\}$, for $j = 1, 2, \dots, \infty$, with suitably normalized eigenvectors, provide an orthonormal basis for $L^2(\Omega)$. We also set $\lambda_j = \mu_j^{-1}$. For $\alpha \geq 0$ and $v \in L^2(\Omega)$,

$$\mathcal{A}^{-\alpha}v = \sum_{j=1}^{\infty} \mu_j^{\alpha} (v, \psi_j) \psi_j.$$

Positive fractional powers of \mathcal{A} are also given by similar series. For $\alpha \geq 0$, define

$$D(\mathcal{A}^{\alpha}) := \left\{ v \in L^2 : \sum_{j=1}^{\infty} \lambda_j^{2\alpha} |(v, \psi_j)|^2 < \infty \right\}$$

and

$$\mathcal{A}^{\alpha}v := \sum_{j=1}^{\infty} \lambda_j^{\alpha} (v, \psi_j) \psi_j \quad \text{for } v \in D(\mathcal{A}^{\alpha}).$$

We consider the fractional order elliptic equation: Find $u \in D(\mathcal{A}^{\alpha})$ satisfying

$$(1.3) \quad \mathcal{A}^{\alpha}u = f \quad \text{for } f \in L^2(\Omega)$$

and note that its solution is given by

$$u = \mathcal{T}^{\alpha}f := \sum_{j=1}^{\infty} \mu_j^{\alpha} (f, \psi_j) \psi_j.$$

Our goal is to approximate u by using finite element or finite differences. The finite element approximation on $V_h \subset V$ is based on the discrete solution operator $\mathcal{T}_h : V_h \rightarrow V_h$ defined by $\mathcal{T}_h v_h := w_h$ where w_h is the unique function in V_h satisfying

$$A(w_h, v_h) = (v_h, v_h), \quad \text{for all } v_h \in V_h.$$

The inverse of \mathcal{T}_h is denoted by \mathcal{A}_h and satisfies

$$(\mathcal{A}_h w_h, v_h) = A(w_h, v_h), \quad \text{for all } v_h \in V_h.$$

We obtain a “semi-discrete” approximation to u of equation (1.3) by defining

$$(1.4) \quad u_h = \mathcal{T}_h^\alpha \pi_h f := \mathcal{A}_h^{-\alpha} \pi_h f,$$

where π_h is the $L^2(\Omega)$ -orthogonal projection into V_h . Note that u_h can be expanded in the $L^2(\Omega)$ -orthogonal eigenfunctions of \mathcal{T}_h , i.e., if $\{\psi_{h,j}, \mu_{h,j}\}$, for $j = 1, \dots, M$, denotes the eigenpairs and M is the dimension of V_h then

$$\pi_h f = \sum_{j=1}^M (f, \psi_{h,j}) \psi_{h,j}$$

and

$$(1.5) \quad u_h = \sum_{j=1}^M \mu_{h,j}^\alpha (f, \psi_{h,j}) \psi_{h,j}.$$

In this paper, we shall study a technique for approximating the solution to (1.4) which avoids computing the eigenvectors and eigenvalues of \mathcal{T}_h .

We note that the technique to be developed can be applied to finite difference approximations as well. In this case, the discrete space is a finite dimensional space of grid point values and $\pi_h f$ is replaced by the interpolant of f at the grid nodes. The matrix \mathcal{T}_h comes from applying finite difference approximations to the derivatives in the strong form (see, (4.1)) of problem (1.2). Its scaling is not arbitrary if we expect $\mathcal{T}_h^\alpha \pi_h f$ to converge to the grid point values of f . This, in turn, implies the proper scaling for the discrete norms.

It has been shown in [5, Theorem 4.3] that, if the operator \mathcal{T} satisfies elliptic regularity pickup with index $s \in (0, 1]$ (see Assumption 4.1) then for appropriate f ,

$$\|u - u_h\| = \|\mathcal{T}^\alpha f - \mathcal{T}_h^\alpha \pi_h f\| = O(h^{2s}).$$

See Section 4 for more details. Here $\|\cdot\|$ denotes the $L^2(\Omega)$ -norm.

Obviously, the discrete operator \mathcal{A}_h is symmetric and positive definite and the corresponding matrix is full. We note that problems involving finding approximations of $\mathcal{A}_h^{1/2}$, cf. [9], evaluating the sign function of \mathcal{A}_h , cf. [12], and other related functions of matrices have a long history in numerical linear algebra.

1.2. The idea of the method of Vabishchevich. In this paper, we develop and study a method for approximating the solution (1.4). Our proposed method is related to an idea of P. Vabishchevich, [23], which exhibits u_h as a solution of a special time dependent problem. Now we briefly explain the idea of his method.

We start with the observation that the unique solution $\hat{u}(t)$ to the ordinary differential equation initial value problem,

$$(1.6) \quad \hat{u}_t + \frac{\alpha(\lambda - \delta)}{\delta + t(\lambda - \delta)} \hat{u} = 0, \quad \hat{u}(0) = \delta^{-\alpha} \hat{v}$$

with $0 < \delta < \lambda$ and $\alpha \geq 0$, is given by

$$(1.7) \quad \hat{u}(t) = (\delta + t(\lambda - \delta))^{-\alpha} \hat{v}$$

and hence

$$(1.8) \quad \hat{u}(1) = \lambda^{-\alpha} \hat{v}.$$

Note also that for $k > 0$,

$$(1.9) \quad \hat{u}(t+k) = [1 + k(\lambda - \delta)/(\delta + t(\lambda - \delta))]^{-\alpha} \hat{u}(t).$$

Now suppose that the spectrum of \mathcal{A}_h is contained in the interval $[\lambda_1, \lambda_M]$ with $\lambda_1 > 0$. Let $0 < \delta < \lambda_1$ and set $\mathcal{B} = \mathcal{A}_h - \delta\mathcal{I}$. We consider the vector valued ODE: Find $U(t) : [0, 1] \rightarrow V_h$ satisfying

$$(1.10) \quad \begin{aligned} U_t + \alpha\mathcal{B}(\delta\mathcal{I} + t\mathcal{B})^{-1}U &= 0, \\ U(0) &= \delta^{-\alpha}f_h \end{aligned}$$

where $f_h := \pi_h f$. Expanding the solution to (1.10) as

$$U(t) = \sum_{j=1}^M c_j(t)\psi_{j,h},$$

we find that $c_j(t)$ solves (1.6) with $\lambda = \lambda_{j,h}$. Moreover, it follows from (1.7) and (1.9) that

$$(1.11) \quad U(t) := (\delta\mathcal{I} + t\mathcal{B})^{-\alpha}f_h$$

and

$$(1.12) \quad U(t+k) = (\mathcal{I} + k\mathcal{B}(\delta\mathcal{I} + t\mathcal{B})^{-1})^{-\alpha}U(t).$$

As proposed by Vabishchevich [23], it is then natural to consider numerical approximations to (1.10) based on a time stepping method.

In [23], Vabishchevich proposed a time stepping scheme based on the backward Euler method and applied it to approximate fractional powers of a discrete approximation \mathcal{A}_h of the Laplace operator with homogeneous Dirichlet boundary conditions. The results of numerical computations illustrating the accuracy, convergence, and some theoretical aspects of the method were provided.

In this paper, we take a different but related approach. Instead of approximating the solution of (1.10), we simply approximate the function $U(t_i)$ given by (1.11) on an increasing sequence of nodes $0 = t_0 < t_1 < \dots < t_K = 1$. We start from the recurrence (1.12). The ‘‘time stepping’’ methods that we shall study are based on diagonal Padé approximation to $(1+x)^{-\alpha}$, i.e.,

$$(1.13) \quad (1+x)^{-\alpha} \approx r_m(x) := \frac{P_m(x)}{Q_m(x)}$$

with P_m and Q_m being polynomials of degree m and $Q_m(0) = 1$. The polynomials P_m and Q_m are then uniquely defined by requiring that the first $2m+1$ terms of the Maclaurin expansion of

$$(1+x)^{-\alpha} - r_m(x)$$

vanish. The method that we study and analyze is given by setting $U_0 := u(0) = \delta^{-\alpha}f_h$ and applying the recurrence

$$(1.14) \quad U_l = r_m(k_l\mathcal{B}(\delta\mathcal{I} + t_{l-1}\mathcal{B})^{-1})U_{l-1}, \quad l = 1, 2, \dots, K$$

with $k_l = t_l - t_{l-1}$. Here U_l is our approximation of $U(t_l)$ so that U_K approximates $U(1) = u_h$. We shall see that these methods are unconditionally stable for $m = 1, 2, \dots$ and $\alpha \in (0, 1)$.

Even though we take a different point of view, we are still solving (1.10), as suggested by P. Vabishchevich, [23]. It is important to note that although Problem (1.10) appears harmless, it behaves considerably different than, for example, the classical parabolic problem:

$$(1.15) \quad w_t + \mathcal{A}_h w = 0.$$

For example, if $w(0) = \psi_{j,h}$ then $w(1) = e^{-\lambda_{j,h}} \psi_{j,h}$ while if $f_h = \psi_{j,h}$, the solution of (1.10) is $u(1) = \mathcal{A}_h^{-\alpha} \psi_{j,h} = \lambda_{j,h}^{-\alpha} \psi_{j,h}$. This means that initial time step errors in the high frequency components for our problem have much stronger effect on the accuracy of the final solution. This is especially important for problems whose solutions have minimal regularity.

1.3. Our contributions. In this paper, we consider two time stepping schemes, one involving mesh refinement near $t = 0$ and the other using a fixed time step. In both cases, we shall be using (1.14) to define our solution but on different meshes in time.

The refinement scheme starts with an initial basic mesh with $t_0 = 0$, $t_i = 2^{i-1-L}$, for $i = 1, 2, \dots, L+1$ with L chosen so that $2^{-L} < (\lambda_M)^{-1}$. Subsequent finer meshes are defined by partitioning each of the above intervals into N equally spaced subdivisions. The refinement scheme leads to an error estimate

$$\|\mathcal{A}_h^{-\alpha} f_h - U_{N(L+1)}\| \leq CN^{-2m} \|f_h\|$$

for the Padé scheme based on $r_m(x)$.

The second scheme that we study is the simpler one using a fixed step size $k_N = 1/N$. In this case, we obtain the error estimate

$$(1.16) \quad \|\mathcal{A}_h^{-\alpha} f_h - U_N\| \leq Ck_N^{\alpha+\gamma} \|A_h^\gamma f_h\|, \quad \text{for } 0 \leq \gamma \leq 2m - \alpha.$$

It is clear that L in the first method grows like the logarithm of λ_M so that more steps are required by the refinement scheme when the same N is used in both. However, in all of our numerical examples, if one adjusts the values of N in both schemes to obtain the same absolute convergence, the refinement scheme requires less steps overall.

The question of when the norm on the right hand side of (1.16) can be controlled by natural norms on the data f is open. Although, such a result for $\gamma \leq 1$ was provided in [15], the result for larger γ is not known even in the finite element case. We discuss this in more detail in Section 4. In fact, our numerical results in Section 5 suggest that the result is not true in general.

2. PADÉ APPROXIMATIONS

In this section, we develop diagonal Padé approximations to $(1+x)^{-\alpha}$ for $\alpha \in (0, 1)$ based on the classical theory of Padé approximations given by Baker [1].

Our approximations are of the form of (1.13) with $m = 1, 2, \dots$ and we shall write down explicit formula for the polynomials $P_m(x)$ and $Q_m(x)$. The starting point is the formula [1, relation (5.2)] or [11, formula (2.1)]:

$$(1+x)^{-\alpha} = {}_2F_1(\alpha, 1; 1; -x).$$

Here ${}_2F_1(a, b; c; x)$ denotes the hypergeometric function defined by

$${}_2F_1(a, b; c; x) = \sum_{j=0}^{\infty} \frac{(a)_j (b)_j}{j! (c)_j} x^j.$$

Here $(a)_0 = 1$ and $(a)_j = a(a+1) \cdots (a+j-1)$ for $j > 0$. This series converges for $|x| < 1$ provide that c is not in $\{0, -1, -2, \dots\}$.

Baker, [1, formula (5.12)], also gives an explicit expression for the denominator:

$$(2.1) \quad \begin{aligned} Q_m(x) &= {}_2F_1(-m, -\alpha - m; -2m; -x) \\ &:= \sum_{j=0}^m \frac{(-m)_j (-\alpha - m)_j}{j! (-2m)_j} (-x)^j = 1 + \sum_{j=1}^m a_j b_j(\alpha) x^j. \end{aligned}$$

Here $b_0(\alpha) = a_0 = 1$,

$$b_j(\alpha) = (m + \alpha)((m - 1) + \alpha) \cdots ((m + 1 - j) + \alpha)$$

and

$$a_j = \frac{m(m-1) \cdots (m+1-j)}{j!(2m(2m-1) \cdots (2m+1-j))} \quad \text{for } j = 1, 2, \dots, m.$$

Now, Theorem 9.2 of [1] implies that $Q_m(x)/P_m(x)$ is the diagonal Padé approximation to $(1+x)^\alpha$ and again applying (5.12) of [1], we find that

$$(2.2) \quad \begin{aligned} P_m(x) &= {}_2F_1(-m, \alpha - m; -2m; -x) \\ &:= \sum_{j=0}^m \frac{(-m)_j (\alpha - m)_j}{j! (-2m)_j} (-x)^j = 1 + \sum_{j=1}^m a_j b_j(-\alpha) x^j. \end{aligned}$$

Using the above formulas, we find, for example:

$$r_1(x) = \frac{1 + [(1 - \alpha)/2]x}{1 + [(1 + \alpha)/2]x}$$

and

$$r_2(x) = \frac{1 + [(2 - \alpha)/2]x + [(2 - \alpha)(1 - \alpha)/12]x^2}{1 + [(2 + \alpha)/2]x + [(2 + \alpha)(1 + \alpha)/12]x^2}.$$

For our further considerations, we need to discuss a relation between the denominators appearing in Padé approximations and orthogonal polynomials with respect to an appropriate weight w . We first note the series expansion of

$$(1 - x)^{-\alpha} = \sum_{i=0}^{\infty} \frac{(\alpha)_i x^i}{i!} := \sum_{i=0}^{\infty} c_i x^i.$$

The coefficients above satisfy

$$(2.3) \quad c_i = \frac{1}{\Gamma(\alpha)\Gamma(1-\alpha)} \int_0^1 x^i \left((1-x)^{-\alpha} x^{\alpha-1} \right) dx := \frac{1}{\Gamma(\alpha)\Gamma(1-\alpha)} \int_0^1 x^i w(x) dx,$$

where $w(x) = (1-x)^{-\alpha} x^{\alpha-1}$. By (7.7) of [1], utilizing the fact that $P_m(-x)/Q_m(-x)$ is the Padé approximation of $(1-x)^{-\alpha}$, we obtain that the denominator $Q_m(x)$ can be expressed by

$$Q_m(x) = (-x)^m q_m(-1/x)$$

where q_m is the monic polynomial of order m which is orthogonal to the set of polynomials of degree less than m with the weight $xw(x)$. As the roots of $q_m(x)$ are all in the interval $(0, 1)$, those of $Q_m(x)$ are in the interval $(-\infty, -1)$.

The expressions for the numerator and denominator in $r_m(x)$ imply the following proposition.

Proposition 2.1. *Let α be in $(0, 1)$ and m be a positive integer. Then, there are positive constants ρ_m satisfying*

$$(2.4) \quad \rho_m \leq r_m(x) \leq 1, \quad \text{for all } x \geq 0.$$

Proof. As α is in $(0, 1)$,

$$0 < b_j(-\alpha) < b_j(\alpha).$$

This means for $x \geq 0$, $a_j b_j(-\alpha)x^j \leq a_j b_j(\alpha)x^j$ with strict inequality when $x > 0$. The second inequality of (2.4) follows by summation.

For the first inequality in (2.4), we note that both $Q_m(x)$ and $P_m(x)$ are positive for $x \geq 0$ and

$$\lim_{x \rightarrow \infty} r_m(x) = b_m(-\alpha)/b_m(\alpha) > 0.$$

The first inequality in (2.4) immediately follows from the fact that $r_m(x)$ is continuous on $[-1, \infty)$ since all of the roots of $Q_m(x)$ are in $(-\infty, -1)$ and takes values in $(0, 1]$ for $x \geq 0$. \square

To clarify further the convergence of these approximations, we include the following proposition.

Proposition 2.2. For $0 \leq s \leq 2m + 1$,

$$(2.5) \quad |(1+x)^{-\alpha} - r_m(x)| \leq c_{m,s} x^s \quad \text{for } x \in [0, \infty)$$

where

$$c_{m,s} = \max\{Q_m(-1)2^{s-2m}, 2^{1+s}\}.$$

Proof. We use Theorem 5 of [11] which gives that

$$\begin{aligned} (1+x)^{-\alpha} - r_m(x) &= \frac{Q_m(-1)}{Q_m(x)} \sum_{n=2m+1}^{\infty} \frac{(\alpha)_n (n-2m)_m}{n! (n+\alpha-m)_m} (-x)^n \\ &:= \frac{Q_m(-1)}{Q_m(x)} (-x)^{2m+1} \sum_{i=0}^{\infty} d_{2m+1+i} (-x)^i. \end{aligned}$$

A simple computation shows that $0 < d_n < 1$ for $n \geq 2m+1$ and so for $|x| < \tau < 1$,

$$\left| \sum_{i=0}^{\infty} d_{2m+1+i} (-x)^i \right| \leq (1-\tau)^{-1}.$$

Thus, for $x \in [0, \tau]$ and $s \in [0, 2m+1]$,

$$\begin{aligned} |r_m(x) - (1+x)^{-\alpha}| &\leq |Q_m(-1)| (1-\tau)^{-1} x^{2m+1} \\ &\leq |Q_m(-1)| \tau^{2m+1-s} (1-\tau)^{-1} x^s. \end{aligned}$$

Finally, for the case $x \in [\tau, \infty)$ by Proposition 2.1,

$$|r_m(x) - (1+x)^{-\alpha}| \leq 2 \leq 2x^s / \tau^s, \quad \text{for } x \in [\tau, \infty)$$

and (2.5) follows by taking $\tau = 1/2$. \square

3. THE TIME STEPPING SCHEMES AND THEIR ANALYSIS

In this section, we define and analyze both equally spaced time stepping schemes as well as schemes employing refinement near the origin. We shall restrict ourselves to the approximating the solution to finite dimensional problem (1.4) described in the introduction even though generalizations to hermitian and non-hermitian bounded operators on infinite dimensional spaces are possible. Recall that $\mathcal{B} = \mathcal{A}_h - \delta \mathcal{I}$ with $\delta \in (0, \lambda_1)$ and that $\|\cdot\|$ and (\cdot, \cdot) denote, respectively, the norm and inner product in $L^2(\Omega)$.

3.1. Time-stepping method on geometrically refined meshes (GRM). We first consider the geometrically refined mesh that is constructed in two steps.

First, we take

$$L = \lceil \log(\lambda_M) / \log(2) \rceil$$

and set $t_i = 2^{i-1-L}$ for $i = 1, \dots, L+1$ and $t_0 = 0$. Note that $t_{L+1} = 1$ and $2^{-L} \leq (\lambda_M)^{-1}$. Next, we define

$$(3.1) \quad k_n = \begin{cases} t_n/N & \text{for } n = 1, \dots, L, \\ t_1/N & \text{when } n = 0. \end{cases}$$

Note that $k_0 = k_1$ and

$$(3.2) \quad k_0 \lambda_M = \frac{2^{-L} \lambda_M}{N} \leq N^{-1}.$$

The grid that we use in our computations is obtained by partitioning each subinterval $I_n = [t_n, t_{n+1}]$, $n = 0, 1, \dots, L$, into N subintervals with end points

$$t_{n,j} := t_n + j k_n \quad \text{for } j = 0, \dots, N.$$

It can be seen that $t_{n,0} = t_n$ and $t_{n,N} = t_{n+1}$, $n = 0, 1, \dots, L$, so that the mesh has totally $(L+1)N$ intervals.

Based on this partitioning, the refined time stepping method for approximating $A_h^{-\alpha} v$ for $v \in V_h$ is given by:

Algorithm 3.1. (a) Set $U_0 = \delta^{-\alpha} v$.

(b) For $n = 0, 1, \dots, L$:

(i) Set $U_{n,0} = U_n$.

(ii) For $j = 1, 2, \dots, N$, set

$$U_{n,j} = r_m(k_n \mathcal{B}(\delta \mathcal{I} + t_{n,j-1} \mathcal{B})^{-1}) U_{n,j-1}.$$

(iii) Set $U_{n+1} = U_{n,N}$.

After executing the above algorithm, U_{L+1} is the approximation to $\mathcal{A}_h^{-\alpha} v$. Note that the notation differs slightly from that used in the introduction. The computation of U_{L+1} requires $K = (L+1)N$ time steps.

The discrete eigenvalues and eigenvectors will play a major role in our analysis so, for notational simplicity, we denote them by $\{\psi_j, \lambda_j\}$ (instead of $\{\psi_{j,h}, \lambda_{j,h}\}$ as in the introduction). We then have

$$v = \sum_{j=1}^M (v, \psi_j) \psi_j.$$

Moreover,

$$\mathcal{A}_h^{-\alpha} v = \sum_{j=1}^M \lambda_j^{-\alpha} (v, \psi_j) \psi_j.$$

The expansion for U_{L+1} is given by

$$U_{L+1} = \sum_{j=1}^M \mu(\lambda_j) (v, \psi_j) \psi_j$$

where the coefficient $\mu(\lambda_j)$ is given by the following algorithm:

Algorithm 3.2. (a) Set $\mu_0 = \delta^{-\alpha}$.

(b) For $n = 0, 1, \dots, L$:

(i) Set $\mu_{n,0} = \mu_n$.

(ii) For $j = 1, 2, \dots, N$, set

$$\mu_{n,j} = r_m(k_n(\lambda - \delta)/(\delta + t_{n,j-1}(\lambda - \delta)))\mu_{n,j-1}.$$

(iii) Set $\mu_{n+1} = \mu_{n,N}$.

(c) Set $\mu(\lambda) = \mu_{L+1}$.

Theorem 3.3. Let N be a positive integer. Then

$$(3.3) \quad |\lambda^{-\alpha} - \mu(\lambda)| \leq \tilde{c}N^{-2m}, \quad \text{for all } \lambda \in [\lambda_1, \lambda_M]$$

and

$$(3.4) \quad \|\mathcal{A}_h^{-\alpha}v - U_{L+1}\| \leq \tilde{c}N^{-2m}\|v\|, \quad \text{for all } v \in V_h.$$

Here \tilde{c} is a constant depending only on δ , m and α .

Proof. Fix λ in $[\lambda_1, \lambda_M]$ and let $\{\mu_n, \mu_{n,j}\}$ be as in Algorithm 3.2. Further, for $n = 0, \dots, L$ and $j = 1, \dots, N$ let

$$v_{n,j} = (\delta + t_{n,j}(\lambda - \delta))^{-\alpha}, \quad e_{n,j} = v_{n,j} - \mu_{n,j}, \quad \text{and} \quad \theta_{n,j} = k_n(\lambda - \delta)/(\delta + t_{n,j-1}(\lambda - \delta)).$$

We note that as in (1.12),

$$v_{n,j} = (1 + \theta_{n,j})^{-\alpha} v_{n,j-1}.$$

Thus,

$$e_{n,j} = r_m(\theta_{n,j})e_{n,j-1} + [(1 + \theta_{n,j})^{-\alpha} - r_m(\theta_{n,j})]v_{n,j-1}$$

and by Proposition 2.1 and 2.2,

$$(3.5) \quad |e_{n,j}| \leq |e_{n,j-1}| + |(1 + \theta_{n,j})^{-\alpha} - r_m(\theta_{n,j})| |v_{n,j-1}|,$$

for $n = 0, 1, \dots, L$ and $j = 1, \dots, N$.

Using $e_0 = 0$, (3.5), Proposition 2.2 and the definition of $v_{n,j-1}$, we have

$$(3.6) \quad \begin{aligned} |\lambda^{-\alpha} - \mu(\lambda)| &= |e_{L+1}| = \sum_{n=0}^L \sum_{j=1}^N \left(|e_{n,j}| - |e_{n,j-1}| \right) \\ &\leq c_{m,2m+1} \sum_{n=0}^L \sum_{j=1}^N \theta_{n,j}^{2m+1} |v_{n,j-1}| \\ &= c_{m,2m+1} \sum_{n=0}^L \sum_{j=1}^N \frac{(k_n(\lambda - \delta))^{2m+1}}{(\delta + t_{n,j-1}(\lambda - \delta))^{2m+\alpha+1}}. \end{aligned}$$

We note that by (3.2),

$$(3.7) \quad \sum_{j=1}^N \frac{(k_0(\lambda - \delta))^{2m+1}}{(\delta + t_{0,j-1}(\lambda - \delta))^{2m+\alpha+1}} \leq \delta^{-2m-\alpha-1} \sum_{j=1}^N N^{-2m-1} = \delta^{-2m-\alpha-1} N^{-2m}.$$

The remaining terms in (3.6) will be bounded by integration. Applying mean value theorem for integration it follows that for some $t_\theta \in [t_{n,j-1}, t_{n,j}]$,

$$\begin{aligned}
& \int_{t_{n,j-1}}^{t_{n,j}} \frac{t^{2m}(\lambda - \delta)^{2m}}{(\delta + t(\lambda - \delta))^{2m+\alpha+1}} dt = \frac{t_\theta^{2m}(\lambda - \delta)^{2m}}{(\delta + t_\theta(\lambda - \delta))^{2m+\alpha+1}} k_n \\
& = \left(\frac{t_\theta}{t_{n,j-1}} \right)^{2m} \left(\frac{\delta + t_{n,j-1}(\lambda - \delta)}{\delta + t_\theta(\lambda - \delta)} \right)^{2m+\alpha+1} \frac{t_{n,j-1}^{2m}(\lambda - \delta)^{2m}}{(\delta + t_{n,j-1}(\lambda - \delta))^{2m+\alpha+1}} k_n \\
& \geq \left(\frac{t_{n,j-1}}{t_\theta} \right)^{\alpha+1} \frac{t_{n,j-1}^{2m}(\lambda - \delta)^{2m}}{(\delta + t_{n,j-1}(\lambda - \delta))^{2m+\alpha+1}} k_n \\
& \geq \left(\frac{N}{N+1} \right)^{\alpha+1} \frac{t_{n,j-1}^{2m}(\lambda - \delta)^{2m}}{(\delta + t_{n,j-1}(\lambda - \delta))^{2m+\alpha+1}} k_n.
\end{aligned}$$

Now $(N+1)/N \leq 2$ and $t_n \leq t_{n,j-1}$ for $j = 1, 2, \dots, N$ so that

$$\begin{aligned}
(3.8) \quad & \frac{(k_n(\lambda - \delta))^{2m+1}}{(\delta + t_{n,j-1}(\lambda - \delta))^{2m+\alpha+1}} = N^{-2m} \frac{t_n^{2m} k_n (\lambda - \delta)^{2m+1}}{(\delta + t_{n,j-1}(\lambda - \delta))^{2m+\alpha+1}} \\
& \leq 2^{\alpha+1} N^{-2m} (\lambda - \delta) \int_{t_{n,j-1}}^{t_{n,j}} \frac{t^{2m}(\lambda - \delta)^{2m}}{(\delta + t(\lambda - \delta))^{2m+\alpha+1}} dt.
\end{aligned}$$

Applying (3.8) to the remaining terms in (3.6) we have

$$\begin{aligned}
(3.9) \quad & \sum_{n=0}^L \sum_{j=1}^N \left(|e_{n,j}| - |e_{n,j-1}| \right) \\
& \leq \delta^{-2m-\alpha-1} N^{-2m} + 2^{\alpha+1} N^{-2m} (\lambda - \delta) \int_0^1 \frac{t^{2m}(\lambda - \delta)^{2m}}{(\delta + t(\lambda - \delta))^{2m+\alpha+1}} dt \\
& \leq \delta^{-2m-\alpha-1} N^{-2m} + 2^{\alpha+1} N^{-2m} \int_0^\infty \frac{z^{2m}}{(\delta + z)^{2m+\alpha+1}} dz.
\end{aligned}$$

As the last integral on the right converges, (3.3) follows combining (3.6), (3.7) and (3.9).

The inequality (3.4) follows immediately from (3.3) and the Parseval's identities:

$$\begin{aligned}
\|\mathcal{A}_h^{-\alpha} v - U_{L+1}\|^2 &= \sum_{j=1}^M |\lambda_j^{-\alpha} - \mu(\lambda_j)|^2 |(v, \psi_j)|^2 \\
&\leq \tilde{c}^2 N^{-4m} \sum_{j=1}^M |(v, \psi_j)|^2 = \tilde{c}^2 N^{-4m} \|v\|^2.
\end{aligned}$$

□

Remark 3.1. For any $s \in \mathbb{R}$ and $v \in V_h$, let

$$(3.10) \quad \|v\|_{s,h} := \left(\sum_{j=1}^M \lambda_j^s |(v, \psi_j)|^2 \right)^{1/2} = \|\mathcal{A}_h^{s/2} v\|.$$

Then, it follows from the proof of the above theorem that for any $s \in \mathbb{R}$,

$$\|\mathcal{A}_h^{-\alpha} v - U_{L+1}\|_{s,h} \leq \tilde{c} N^{-2m} \|v\|_{s,h}.$$

3.2. Time-stepping method on uniform meshes (UM). We next consider uniform time stepping. In this case, given a positive integer N , we set $k_N = 1/N$ and $t_n = nk_N$. The approximation is obtained from the recurrence

$$(3.11) \quad \begin{aligned} U_0 &= \delta^{-\alpha} v \in V_h, \\ U_n &= r_m(k_N \mathcal{B}(\delta \mathcal{I} + t_{n-1} \mathcal{B})^{-1}) U_{n-1}, \quad \text{for } n = 1, 2, \dots, N. \end{aligned}$$

In this case, U_N is our approximation to $\mathcal{A}_h^{-\alpha} v$. The analysis of the error requires the following proposition.

Proposition 3.4. *For $\lambda \geq \delta$, set*

$$(3.12) \quad \theta_n = \frac{k_N(\lambda - \delta)}{\delta + t_{n-1}(\lambda - \delta)}.$$

Then for $q \geq p > 1$,

$$(3.13) \quad \prod_{n=p}^q r_m(\theta_n) \leq c \prod_{n=p}^q (1 + \theta_n)^{-\alpha},$$

with c depending only on m and α .

Proof. We note that for $n > 1$, $\theta_n \leq (n-1)^{-1} \in [0, 1]$. By Proposition 2.2,

$$\begin{aligned} r_m(\theta_n) &\leq (1 + \theta_n)^{-\alpha} + c_{m,2m+1} |\theta_n|^{2m+1} \\ &\leq (1 + \theta_n)^{-\alpha} (1 + 2^\alpha c_{m,2m+1} (n-1)^{-2m-1}) \end{aligned}$$

and hence

$$\frac{r_m(\theta_n)}{(1 + \theta_n)^{-\alpha}} \leq (1 + 2^\alpha c_{m,2m+1} (n-1)^{-2m-1}).$$

Thus, for $q \geq p > 1$,

$$\prod_{n=p}^q \frac{r_m(\theta_n)}{(1 + \theta_n)^{-\alpha}} \leq \prod_{n=p}^q (1 + 2^\alpha c_{m,2m+1} (n-1)^{-2m-1}) \leq c$$

with

$$c = \prod_{j=1}^{\infty} (1 + 2^\alpha c_{m,2m+1} j^{-2m-1}).$$

□

Theorem 7.2 of [22] provides error estimates for single step approximations for the standard parabolic problem (1.15) with non-smooth initial data. The next theorem has the same flavor however differs significantly as the solutions of our problem exhibit less regularity.

Theorem 3.5. *Let $N > 1$, $v \in V_h$ and U_N be defined by (3.11). Then, for $\gamma \geq 0$ and $\alpha + \gamma \leq 2m$,*

$$(3.14) \quad \|\mathcal{A}_h^{-\alpha} v - U_N\| \leq \tilde{c} k_N^{\alpha+\gamma} \|\mathcal{A}_h^\gamma v\|$$

with \tilde{c} depending only on α , m , γ , and δ . As in Remark 3.1, the left hand norm above can be replaced by $\|\cdot\|_{h,r}$ provided that the right is replaced by $\|\mathcal{A}_h^\gamma v\|_{h,r}$.

Proof. In this proof, c denotes a generic positive constant only depending on α , γ , m and δ . We fix $\lambda \geq \delta$ and define, for $j \geq l \geq 1$,

$$r_m^{j,l}(\lambda) := r_m^{j,l} = r_m(\theta_j) r_m(\theta_{j-1}) \cdots r_m(\theta_l)$$

and

$$w^{j,l}(\lambda) := w^{j,l} = (1 + \theta_j)^{-\alpha} (1 + \theta_{j-1})^{-\alpha} \cdots (1 + \theta_l)^{-\alpha}.$$

Finally, we set

$$e_N(\lambda) := e_N = (w^{N,1} - r_m^{N,1})\delta^{-\alpha}.$$

We note that it is a consequence of (1.8) and (1.9) that

$$(3.15) \quad \delta^{-\alpha} w^{N,1} = \lambda^{-\alpha}.$$

For any $j > 1$,

$$w^{j,1} - r_m^{j,1} = [(1 + \theta_j)^{-\alpha} - r_m(\theta_j)]w^{j-1,1} + r_m(\theta_j)[w^{j-1,1} - r_m^{j-1,1}].$$

Repeated application of this identity leads to

$$(3.16) \quad \begin{aligned} e_N &= \delta^{-\alpha} [w^{N,1} - r_m^{N,1}] \\ &= \delta^{-\alpha} [(1 + \theta_N)^{-\alpha} - r_m(\theta_N)]w^{N-1,1} \\ &\quad + \delta^{-\alpha} r_m(\theta_N) [(1 + \theta_{N-1})^{-\alpha} - r_m(\theta_{N-1})]w^{N-2,1} \\ &\quad + \cdots \\ &\quad + \delta^{-\alpha} r_m^{N,2} [(1 + \theta_1)^{-\alpha} - r_m(\theta_1)]. \end{aligned}$$

Proposition 3.4 implies that for $j \geq 2$,

$$(3.17) \quad |r_m^{N,j}| \leq c w^{N,j}.$$

We first bound the last term of (3.16) by applying this and (3.15) to obtain

$$(3.18) \quad \begin{aligned} T_1 &:= \delta^{-\alpha} |r_m^{N,2} [(1 + \theta_1)^{-\alpha} - r_m(\theta_1)]| \leq c \delta^{-\alpha} w^{N,2} |(1 + \theta_1)^{-\alpha} - r_m(\theta_1)| \\ &= c \lambda^{-\alpha} (1 + \theta_1)^\alpha |(1 + \theta_1)^{-\alpha} - r_m(\theta_1)|. \end{aligned}$$

When $\theta_1 \leq 1$, Proposition 2.2 with $s = \alpha + \gamma$ gives,

$$T_1 \leq c \theta_1^{\alpha+\gamma} \lambda^{-\alpha}.$$

When $\theta_1 > 1$, since $\gamma \geq 0$,

$$T_1 \leq c (1 + \theta_1)^\alpha \lambda^{-\alpha} \leq c \theta_1^{\alpha+\gamma} \lambda^{-\alpha}.$$

Thus, in either case, since $\theta_1 = k_N(\lambda - \delta)/\delta \leq k_N \lambda/\delta$,

$$(3.19) \quad T_1 \leq c k_N^{\alpha+\gamma} \lambda^\gamma.$$

The absolute value of the other terms in (3.16) are given by

$$T_j := |r_m^{N,j+1} [(1 + \theta_j)^{-\alpha} - r_m(\theta_j)] w^{j-1,1}|, \quad \text{for } j = 2, 3, \dots, N,$$

where we have defined $r_m^{N,N+1} = 1$ for convenience of notation. Similar to (3.18), we have

$$T_j \leq c \lambda^{-\alpha} (1 + \theta_j)^\alpha |(1 + \theta_j)^{-\alpha} - r_m(\theta_j)|.$$

In this case, θ_j is in $[0, 1]$ and we apply Proposition 2.2 with $s = 1 + \alpha + \gamma$ to obtain

$$T_j \leq c \lambda^{-\alpha} \theta_j^{1+\alpha+\gamma} \leq c \frac{k_N(\lambda - \delta) k_N^{\alpha+\gamma} \lambda^\gamma}{(\delta + t_{j-1}(\lambda - \delta))^{1+\alpha+\gamma}}.$$

Thus,

$$(3.20) \quad \sum_{j=2}^N T_j \leq c(\lambda - \delta) k_N^{\alpha+\gamma} \lambda^\gamma \int_0^1 (\delta + t(\lambda - \delta))^{-1-\alpha-\gamma} dt \leq c k_N^{\alpha+\gamma} \lambda^\gamma.$$

Combining (3.19) and (3.20) gives

$$|e_N(\lambda)| \leq c k_N^{\alpha+\gamma} \lambda^\gamma.$$

We note that by (3.15),

$$\mathcal{A}_h^{-\alpha} v = \delta^{-\alpha} \sum_{j=1}^M w^{N,1}(\lambda_j)(v, \psi_j) \psi_j \quad \text{and} \quad U_N = \delta^{-\alpha} \sum_{j=1}^M r_m^{N,1}(\lambda_j)(v, \psi_j) \psi_j.$$

Thus,

$$\begin{aligned} \|\mathcal{A}_h^{-\alpha} v - U_N\|^2 &= \sum_{j=1}^M |e_N(\lambda_j)|^2 |(v, \psi_j)|^2 \\ &\leq c k_N^{2\alpha+2\gamma} \sum_{j=1}^M \lambda_j^{2\gamma} |(v, \psi_j)|^2 = c k_N^{2\alpha+2\gamma} \|\mathcal{A}_h^\gamma v\|^2 \end{aligned}$$

and this completes the proof. \square

As seen in the above theorem, the discrete regularity of the solution determines the rate of convergence for the uniform step size time stepping method. To some extent, the regularity of the discrete solution is related to the regularity properties of the continuous problem which is being approximated. This will be discussed in the next section.

4. FINITE ELEMENT APPROXIMATION TO FRACTIONAL POWERS OF SECOND ORDER ELLIPTIC OPERATORS

We start with the second order elliptic problem associated with the bilinear form (1.1) of the introduction, namely the boundary value problem:

$$(4.1) \quad \begin{aligned} -\nabla \cdot (a(x) \nabla w) + q(x) w &= f, & \text{for } x \in \Omega, \\ w(x) &= 0, & \text{for } x \in \partial\Omega. \end{aligned}$$

Here $q(x)$, $a(x)$ and Ω are as in the introduction. The bilinear form (1.1) results from (4.1) in the usual way, i.e., integration against a test function and integration by parts.

We start by providing some results for the error between the semi-discrete approximation u_h given by (1.4) and the solution u of (1.3). These results depend on the following regularity condition:

Assumption 4.1. \mathcal{T} satisfies elliptic regularity pickup with index $s \in (0, 1]$, that is

(a) For $f \in H^{-1+s}(\Omega)$, $\mathcal{T}f$ is in $H^{1+s}(\Omega)$ and there is a constant c not depending on f satisfying

$$\|\mathcal{T}f\|_{H^{1+s}(\Omega)} \leq c \|f\|_{H^{-1+s}(\Omega)}.$$

(b) $\mathcal{A} = \mathcal{T}^{-1}$ is a bounded map of $H^{1+s}(\Omega)$ into $H^{-1+s}(\Omega)$.

Remark 4.1. In [5], it has been shown that this implies

$$D(\mathcal{A}^{t/2}) = H_0^1(\Omega) \cap H^t(\Omega), \quad \text{for } t \in [1, 1+s]$$

with equivalent norms.

The above remark shows that $D(\mathcal{A}^{t/2})$ coincides with a Sobolev space of index t . Accordingly, we introduce the notation

$$\dot{H}^t = D(\mathcal{A}^{t/2}), \quad \text{for } t \geq 0.$$

A detailed estimation of the error $u - u_h = \mathcal{T}^\alpha f - \mathcal{T}_h^\alpha \pi_h f$ can be found in [5, Theorem 4.3] and is summarized below (see also, [7] for the case when $s = 1$).

Theorem 4.1. (see, [5, Theorem 4.3]) *Let Assumption 4.1 hold and assume that the mesh is globally quasi-uniform so that the inverse inequality holds, e.g. [22] or [5, inequality (45)]. Set $\beta = s - \alpha$ when $s > \alpha$ and $\beta = 0$ when $s \leq \alpha$. For $\gamma \geq \beta$, there is a constant C uniform in h such that*

$$(4.2) \quad \|\mathcal{T}^\alpha f - \mathcal{T}_h^\alpha \pi_h f\| \leq C_{h,\gamma} h^{2s} \|f\|_{\dot{H}^{2\gamma}} \quad \text{for all } f \in \dot{H}^{2\gamma},$$

where

$$C_{h,\gamma} = \begin{cases} C \log(1/h), & \text{when } \gamma = \beta \text{ and } s \geq \alpha, \\ C, & \text{when } \gamma > \beta \text{ and } s \geq \alpha, \\ C, & \text{when } \alpha > s. \end{cases}$$

As we see from this theorem, the rate of convergence in the $L^2(\Omega)$ -norm is the result of an interplay between the fractional order α , the regularity pick up s of the solution of problem (1.3), and the regularity of the right hand side f . The bottom line is that one recovers optimal convergence rate $O(h^{2s})$ for $\alpha > s$ when $f \in L^2(\Omega)$. However, if $\alpha < s$, the solution is not in $H^{2s}(\Omega)$ without extra regularity from f so this additional smoothness is needed to get the same rate.

Now if we approximate the problem (1.4) using the method of Vabishchevich on the geometrically refined mesh as described in Algorithm 3.1, we get the following bound for the total error (approximation by finite elements and time-stepping):

Corollary 4.2. *Assume the conditions of Theorem 4.1 hold. Then U_{L+1} , obtained by Algorithm 3.1 with $v = \pi_h f$, $\mathcal{B} = \mathcal{A}_h - \delta\mathcal{I}$ and performing $K = (L+1)N$ steps, satisfies*

$$\|\mathcal{T}^\alpha f - U_{L+1}\| \leq C(h^{2s} \|f\|_{\dot{H}^{2\gamma}} + N^{-2m} \|f\|).$$

Corollary 4.3. *Assume the conditions of Theorem 4.1 hold. Then U_N , obtained by applying (3.11) with $v = \pi_h f$ and $\mathcal{B} = \mathcal{A}_h - \delta\mathcal{I}$, satisfies*

$$\|\mathcal{T}^\alpha f - U_N\| \leq C(h^{2s} \|f\|_{\dot{H}^{2\gamma}} + N^{-\alpha-\beta} \|\mathcal{A}_h^\beta \pi_h f\|), \quad \text{for } 0 \leq \beta \leq 2m - \alpha.$$

We next consider the question of bounding the norm $\|\mathcal{A}_h^\beta \pi_h f\|$ in terms of the regularity of f . For $\beta \in [0, 1/2]$, this reduces to showing that the $L^2(\Omega)$ -projector into V_h is a bounded operator on $H_0^1(\Omega)$ with bound independent of h . For globally quasi-uniform meshes, this result is given in [2, 6] while the case of certain refined meshes is given in [3]. When the H^1 bound holds, by interpolation, there is a constant c depending only on $\beta \in [0, 1/2]$ satisfying

$$(4.3) \quad \|\mathcal{A}_h^\beta \pi_h v\| \leq c \|\mathcal{A}^\beta v\|, \quad \text{for all } v \in D(\mathcal{A}^\beta).$$

We extend the above inequality to $\beta \in [1/2, (1+s)/2]$ in the next lemma whose proof is included for completeness as it was already observed in [15].

Lemma 4.4. *Assume that Assumption 4.1 holds and that the mesh is globally quasi-uniform. Then there is a constant c depending on $\beta \in [1/2, (1+s)/2]$ such that (4.3) holds.*

Proof. Let $P_h : H_0^1(\Omega) \rightarrow V_h$ denote the elliptic projector, i.e., $P_h w = w_h \in V_h$ is the unique solution of

$$A(w_h, \theta_h) = A(w, \theta_h), \quad \text{for all } \theta_h \in V_h.$$

Without loss of generality, we can take the norm on $H_0^1(\Omega)$ to be

$$\|v\|_{H^1(\Omega)} = A(v, v)^{1/2} = \|\mathcal{A}^{1/2}v\|.$$

We then have

$$\|\mathcal{A}_h^{1/2}P_h w\| = \|P_h w\|_{H^1(\Omega)} \leq \|w\|_{H^1(\Omega)} = \|\mathcal{A}^{1/2}w\|,$$

for all $w \in H_0^1(\Omega) = D(\mathcal{A}^{1/2})$, while the identity $\mathcal{A}_h P_h v = \pi_h \mathcal{A} v$ for $v \in D(\mathcal{A})$ implies that

$$\|\mathcal{A}_h P_h v\| = \|\pi_h \mathcal{A} v\| \leq \|\mathcal{A} v\|, \quad \text{for all } v \in D(\mathcal{A}).$$

It follows by interpolation that for $r \in [1/2, 1]$,

$$\|\mathcal{A}_h^r P_h v\| \leq \|\mathcal{A}^r v\|, \quad \text{for all } v \in D(\mathcal{A}^r).$$

Now for $t \in [1, 1+s]$, Remark 4.1 implies that for $\dot{H}^t = D(\mathcal{A}^{t/2}) = H^t(\Omega) \cap H_0^1(\Omega)$. Thus, for $v \in \dot{H}^t$,

$$\|\pi_h v\|_{h,t} \leq \|(\pi_h - P_h)v\|_{h,t} + \|P_h v\|_{h,t} \leq C(h^{1-t}\|(\pi_h - P_h)v\|_{H^1(\Omega)} + \|v\|_{\dot{H}^t(\Omega)})$$

where we also used the inverse inequality for the last inequality above. The inequality (4.3) for $\beta = t/2 \in [1/2, (1+s)/2]$ follows from the above inequality, the triangle inequality and the well know error estimates

$$\|(I - \pi_h)v\|_{H^1(\Omega)} + \|(I - P_h)v\|_{H^1(\Omega)} \leq ch^{t-1}\|v\|_{\dot{H}^t(\Omega)}.$$

□

5. NUMERICAL EXAMPLES

In this section, we present numerical examples for the problem coming from (1.1) with $a(x) = 1$, $q(x) = 0$ and $\Omega \subset \mathbb{R}^d$, for $d = 1, 2$.

5.1. One dimensional examples: $\Omega = (0, 1)$. We will consider approximating the solution of (1.3) with the following choices of f :

- (a) $f = \exp(-1/x - 1/(1-x) + 4)$ so that $f \in \dot{H}^s$ for any s .
- (b) $f = x(1-x)$ so that $f \in \dot{H}^s$ for $s < \frac{5}{2}$.
- (c) $f = \min(x, 1-x)$ so that $f \in \dot{H}^s$ for $s < \frac{3}{2}$.
- (d) $f = 1$, so that $f \in \dot{H}^s$ for $s < \frac{1}{2}$.

We note that $f = 1$ fails to be in $\dot{H}^{1/2}$ since functions in $\dot{H}^{1/2}$ vanish at $x = 0$ and $x = 1$.

The first set of runs demonstrate the time stepping error behavior using the geometric refined time stepping algorithm (GRM) and the uniform time stepping scheme (UM) for various α and N . In this case, we use a fixed equally spaced mesh with $h = 1/1000$ and $L = \lceil 2 \log h / \log 2 \rceil$. The total number of time steps for the GRM scheme is thus $(L+1)N$, with $N = 1, 2, 4, 8, \dots$. To make the comparison

more meaningful, we report the errors obtained using the UM and GRM algorithms as a function of the number of solves.

For the first plot, we use f given by (c) above and $\alpha = 0.1, 0.5, 0.9$. Figure 1 gives log-log plots of the relative L^2 error between $u_h = \mathcal{A}_h^{-\alpha} \pi_h f$ and the result obtained using the refined and uniform time stepping schemes with $m = 1$ (left plot) and $m = 2$ (right plot) as a function of the number of solves. Note that the GRM method leads to smaller error using the same number of solves. Plots for f given by (b) and (d) are similar and are omitted.

FIGURE 1. Case (c): relative L^2 error on geometrically refined mesh (GRM) and uniform mesh (UM) for $m = 1$ (left) and $m = 2$ (right).

To further demonstrate that the numerical results reflect the theoretical results proved earlier, we report the approximate order of convergence going from $N = n$ to $N = 2n$,

$$(5.1) \quad \text{Approximate order} := \log(E_n/E_{2n})/\log(2).$$

We used $n = 8$ for both the UM runs and the GRM runs. The reason that we chose this n for this computation is that the errors were getting so small in the GRM algorithm for $N \geq 32$ that, we suspect, computer round off was effecting their significance.

TABLE 1. Approximate order vs. theoretical convergence rates for $m = 1$.

| α | GRM scheme. | | | UM scheme. | | |
|------------|-------------|---------|---------|------------|------------|------------|
| | 0.1 | 0.5 | 0.9 | 0.1 | 0.5 | 0.9 |
| f by (a) | 2.00(2) | 2.00(2) | 2.00(2) | 1.87(2) | 1.95(2) | 1.99(2) |
| f by (b) | 2.00(2) | 2.00(2) | 2.00(2) | 1.34(1.35) | 1.71(1.75) | 1.94(2) |
| f by (c) | 2.00(2) | 2.00(2) | 2.00(2) | 0.85(0.85) | 1.25(1.25) | 1.63(1.65) |
| f by (d) | 2.00(2) | 2.00(2) | 2.00(2) | 0.40(0.35) | 0.77(0.75) | 1.16(1.15) |

We report the approximate order of convergence computed using (5.1) and compare it with the theoretical rate (in parenthesis) in Table 1 and Table 2. Note that the approximate order of convergence was under the assumption that inequality (4.3) holds. Table 1 and Table 2 give the rates when $m = 1$ and $m = 2$, respectively for varying α and f given above. In most cases, the computed order is in good agreement with the theoretical rate for both the refinement and uniform time stepping schemes. In contrast, the theoretical rate of the smooth problem (for f given by (a)) would be $2m$ if (4.3) held. The results in Table 2 suggests that (4.3) does not hold uniformly for $\beta = 4 - \alpha$. In all of the above examples, the error observed for the refinement scheme as a function of the number of solves was below that of the uniform time stepping scheme.

TABLE 2. Approximate order vs. theoretical convergence rates, $m = 2$.

| α | GRM scheme. | | | UM scheme. | | |
|------------|-------------|---------|---------|------------|------------|------------|
| | 0.1 | 0.5 | 0.9 | 0.1 | 0.5 | 0.9 |

Note that the convergence of the GRM schemes is more robust than that of the UM schemes. The GRM schemes always yield $2m$ 'th order convergence while the convergence rate of UM schemes are related to the parameter α and the (discrete) regularity of the initial data v as suggested by the theory. The advantages of the refinement scheme are especially evident for the non-smooth initial data problem.

5.2. A spatial refinement example. The last one dimensional example is for $f = 1$ but uses a sequence of refined spatial grids. By (4.1), the semi-discrete error for an unrefined mesh is $O(h^{2s})$ for $s < 1/4 + \alpha$. As the singular behavior is at the endpoints of the interval, it is natural to use refinement there to try to improve the error behavior. We consider a mesh resulting from a geometric refinement near 0 and 1 similar to the geometric time stepping refinement at 0. Specifically, our meshes on $[0, 1/2]$ are constructed by restricting the mesh of Subsection 3.1 to $[0, 1/2]$ as a function of N , the number of points per interval. In this construction, we choose L so that $2^{-L} \leq h^{-2}$ where $h = 1/4N$ is the mesh size on $[1/4, 1/2]$. The mesh on $[1/2, 1]$ is obtained by reflecting the mesh on $[0, 1/2]$ about $1/2$. The number of mesh points in space is $O(h^{-1} \log(1/h))$.

Table 3 reports errors using the GRM and UM time stepping schemes applied to the case when \mathcal{A}_h comes from a sequence of refined spatial meshes as discussed above. For brevity, we only report results for $\alpha = 0.5$. For each spatial mesh, we compute an accurate approximation $u_{h,ref}$ to the semi-discrete solution $u_h = \mathcal{A}_h^{-\alpha} \pi_h f$ by using a highly refined (in time) 4th order GRM time-stepping scheme. We then report the semi-discrete error norm $e_{semi} := \|I_h(u) - u_{h,ref}\|$ where I_h denotes the finite element interpolation operator on the refined spatial mesh. The solution u is computed at the nodes by using 800000 terms in its Fourier series expansion. The error e_{semi} is important as it gives us an idea how small we need to make the time stepping error so that the overall error is, for example, less than or equal to $2e_{semi}$. In Table 3, nx is the number of intervals in the spatially refined grid, NS is the number of time steps used to reduce the GRM error $E_{GRM} := \|u_{GRM} - u_{h,ref}\|$ below e_{semi} and $E_{UM} := \|u_N - u_{h,ref}\|$ is the UM error for $N = 10^5$ time steps. It is clear that the uniform time stepping method is inefficient for this problem. Indeed, in many cases, the uniform time stepping fails to reduce the error below e_{semi} even when using 10^5 time steps.

TABLE 3. Error and the number of steps for the local refinement in space.

| N | nx | e_{semi} | $m = 1$ | | | $m = 2$ | | |

| 64 | 2176 | 2.68×10^{-6} | 8.79×10^{-7} | 3008 | 2.78×10^{-5} | 4.15×10^{-7} | 188 | 1.47×10^{-5} |
| 128 | 4864 | 6.71×10^{-7} | 2.19×10^{-7} | 6784 | 2.77×10^{-5} | 4.15×10^{-7} | 212 | 1.47×10^{-5} |

5.3. Two dimensional examples: $\Omega = (0, 1)^2$. In the two dimensional case, we consider f given by:

- (e) $f(x, y) = x(1-x)y(1-y)$ so that $f \in \dot{H}^s$ for $s < 5/2$;
(f) $f(x, y) = \begin{cases} 1 & 0.25 \leq x, y \leq 0.75, \\ 0 & \text{otherwise,} \end{cases}$ so that $f \in \dot{H}^s$ for $s < 1/2$.

For brevity, we only report results for the case of $m = 2$. For all runs, we use a uniform mesh in space of size $h = 1/100$ and $L = 14$ in the GRM case. We report the relative error of the time stepping solution compared with $u_h = \mathcal{A}_h^{-\alpha} \pi_h f$. Table 4 gives the errors as a function of α and NS , the number of time steps, for the uniform stepping approximation while those of Table 5 are for the geometric stepping approximation. Similar to 1-D case, the reported convergence rates are obtained by (5.1) using $n := NS = 8 \times 15$ with the theoretical rates in parenthesis.

6. CONCLUSIONS

We proposed two time-stepping methods based on Padé approximation for solving a special pseudo-parabolic equation introduced by Vabishchevich for solving equations involving powers of symmetric positive elliptic operators. We consider two schemes that use geometrically refined and uniform meshes in time. The scheme that uses geometrically refined mesh has a convergence rate that does not depend on the smoothness of the solution, while the scheme involving uniform time-mesh depends crucially on the discrete regularity of the solution. Both, the theoretical

estimates and the numerical tests show that the scheme on geometrically refined meshes is more efficient compared with the uniform time-stepping scheme, especially in the non-smooth data case.
