1. Introduction

In this paper, we study the arithmetic of primary Burniat surfaces. These are certain surfaces of general type first constructed by Burniat [Bur66] in the 1960s as smooth bidouble covers of a del Pezzo surface of degree 6. Their moduli space forms an irreducible connected component of the moduli space of surfaces of general type that is normal and rational of dimension 4, as shown by Bauer and Catanese [BC11]. Their proof makes use of the fact (also proved in the same paper) that Burniat’s surfaces can also be obtained as étale quotients of certain hypersurfaces in products of three elliptic curves, a construction first considered by Inoue [Ino94]. It is this description that allows us to show that Lang’s Conjectures on rational points on varieties of general type hold for primary Burniat surfaces. In fact, we recall a more general statement for projective varieties admitting an étale covering, which embeds in a product of abelian varieties and a product of curves of genus at least two. In particular this applies for certain so-called Inoue type varieties, see Section 2.

After recalling the two different constructions of primary Burniat surfaces in Section 3, we produce an explicit description of their moduli space as an open subset of \( \mathbb{A}^6 \). We then use this description to classify the possible automorphism groups of primary Burniat surfaces. Generically, this automorphism group is \( (\mathbb{Z}/2\mathbb{Z})^2 \), but its order can get as large as 96; see Section 4.

By the general theorem given in Section 2, we know that the set of rational points on a primary Burniat surface \( S \) consists of the points lying on the finitely many curves of geometric genus \( \leq 1 \) on \( S \), together with finitely many ‘sporadic’ points. To describe this set \( S(\mathbb{Q}) \) explicitly, we therefore need to determine the set of low-genus curves on \( S \). This is done in Section 6. The result is that \( S \) does not contain rational curves, but does always contain six smooth elliptic curves, and may contain up to six further (singular) curves of geometric genus 1.

In the last part of the paper, we discuss how the set \( S(\mathbb{Q}) \) can be determined explicitly for a primary Burniat surface \( S \) defined over \( \mathbb{Q} \). We restrict to the

Date: February 25, 2015.

This work was done in the framework of the DFG Research Unit 790 Classification of algebraic surfaces and compact complex manifolds.
case that the three genus 1 curves whose product contains the étale cover $X$ of $S$ are individually defined over $\mathbb{Q}$. We can then write down equations for $X$ of a somewhat more general, but similar form as those used in Section 4 where we were working over $\mathbb{C}$. We explain how to determine the finitely many twists of the covering $X \to S$ that may give rise to rational points on $S$, see Section 7, and we discuss what practical methods are available for the determination of the sets of rational points on these twists, see Section 8. We conclude with a number of examples.

2. Rational points on varieties of general type

We start giving a short account on some conjectures, which were formulated by S. Lang\textsuperscript{1} [Lan86] after discussions with and input from several other mathematicians.

**Conjecture 2.1** (Weak Lang Conjecture). If $X$ is a smooth projective variety of general type defined over a number field $K$, then the set $X(K)$ of $K$-rational points on $X$ is not Zariski-dense in $X$.

For $X$ as in this conjecture, one defines the *exceptional set* $N$ of $X$ as the union of all the images of non-constant morphisms $f : A \to X$ from an abelian variety $A$ to $X$, defined over $\bar{K}$.

**Conjecture 2.2** (Strong Lang Conjecture). Let $X$ be a smooth projective variety of general type defined over a number field $K$. The exceptional set $N$ of $X$ is a proper closed subvariety of $X$, and for each finite field extension $K \subset L$, the set $X(L) \setminus N(L)$ is finite.

In general these conjectures are wide open. They hold for curves (by Faltings’ proof of the Mordell Conjecture), and more generally for subvarieties of abelian varieties, see [Fal94]. However, even in these cases it is far from clear that a suitable explicit description of $X(K)$ can actually be determined. In the case of curves, there has been considerable progress in recent years (see for example [Sto07]), indicating that an effective (algorithmic) solution might be possible.

It is therefore natural to consider the case of surfaces next, where so far only very little is known.

Let $S$ be a smooth projective surface of general type over a number field $K$. In this case, Conjectures 2.1 and 2.2 state that there are only finitely many curves of geometric genus zero or one on $S$ (possibly defined over larger fields) and that the set of $K$-rational points on $S$ outside these curves is finite. We call the curves

\textsuperscript{1}Sometimes these conjectures are referred to as ‘Bombieri-Lang Conjectures’, but Enrico Bombieri insists that he only ever made these conjectures for surfaces.
of geometric genus at most 1 on \( S \) the \textit{low-genus curves} on \( S \), and we call the \( K \)-rational points outside the low-genus curves \textit{sporadic \( K \)-rational points} on \( S \).

An explicit description of \( S(K) \) would then consist of the finite list of the low-genus curves on \( S \), together with the finite list of sporadic \( K \)-rational points. Given a class of surfaces of general type, it is therefore natural to proceed in the following way:

1. prove the finiteness of the set of low-genus curves on surfaces in the class;
2. develop methods for determining this set explicitly;
3. prove the finiteness of the set of sporadic \( K \)-rational points on surfaces in the class;
4. develop methods for determining the set of sporadic points explicitly.

Regarding point (1), the statement was proved by Bogomolov in the 1970s \[\text{Bog77}\] under the condition that the following inequality is satisfied:

\[
c_2(S) = K^2_S > c_2(S), \quad \text{or equivalently,} \quad K^2_S > 6 \chi(S).
\]

Under the same assumption, Miyaoka \[\text{Miy08}\] gave an upper bound for the canonical degree \( K_S \cdot C \) of a curve \( C \) of geometric genus \( \leq 1 \) on \( S \). Moreover, S. Lu \[\text{Lu10}\] proved the following:

\textbf{Theorem 2.3 (Lu).} Let \( S \) be a smooth projective surface of general type over the complex numbers with irregularity \( q(S) \geq 2 \). Then \( S \) admits a proper Zariski closed subset that contains all nontrivial holomorphic images of \( \mathbb{C} \).

In particular, \( S \) contains only a finite number of curves of genus \( \leq 1 \). Lu also gives an explicit bound for the canonical degree of curves of geometric genus \( \leq 1 \) if \( S \) is minimal and has maximal Albanese dimension.

\textbf{Remark 2.4.} Observe that the above statement remains true under the weaker assumption that \( S \) admits a finite \'{e}tale covering \( \tilde{S} \rightarrow S \) such that \( q(\tilde{S}) \geq 2 \).

We recall the following two results due to Faltings \[\text{Fal94}\] and (originally for curves, but the statement generalizes, see for example \[\text{Ser97, \S4.2}\]) to Chevalley and Weil \[\text{CW32}\].

\textbf{Theorem 2.5 (Faltings).} Let \( A \) be an abelian variety over a number field \( K \) with \( X \subset A \) a closed subvariety. Then there are finitely many translates \( X_i = x_i + B_i \) of \( K \)-rational abelian subvarieties \( B_i \subset A \) such that \( X_i \subset X \) and such that each \( K \)-rational point of \( X \) lies on one of the \( X_i \).

\textbf{Theorem 2.6 (Chevalley-Weil).} Let \( X \) be a smooth projective variety defined over a number field \( K \) and let \( \pi : \hat{X} \rightarrow X \) be a finite \'{e}tale covering over \( K \). Then there is a finite extension \( K'/K \) such that \( X(K) \subset \pi(\hat{X}(K')) \).

We need also the following result due to Kawamata \[\text{Kaw80, Theorem 4}\].
Theorem 2.7 (Kawamata). Let $X \subset A$ be a subvariety of an abelian variety over $\mathbb{C}$, which is of general type. Let
\[ Y := \bigcup \{ Z : Z \text{ is the translate of an abelian subvariety of } A, Z \subset X, \dim Z > 0 \}. \]
Then $Y$ is a proper Zariski closed subset of $X$.

Together with Faltings’ theorem this implies that Conjecture 2.2 holds for subvarieties (of general type) of abelian varieties.

We now combine these ingredients to obtain a proof of the following statement (see also [HS00, Prop. F.5.2.5 (ii)] for the ‘weak’ form).

Theorem 2.8. Let $X$ be a smooth projective variety of general type over a number field $K$ which admits a finite étale covering $\pi: \hat{X} \to X$ such that $\hat{X}$ is contained in a product $Z$ of abelian varieties and curves of higher genus (i.e., $\geq 2$).

(1) $X(K)$ is not Zariski dense in $X$.
(2) If $\hat{X}$ does not contain any translate of a positive dimensional abelian subvariety of the abelian part of $Z$, then $X(K)$ is finite.
(3) $X$ satisfies Conjecture 2.2.

Proof. Theorem 2.6 shows that there is a finite field extension $K'/K$ such that $X(K) \subset \pi(\hat{X}(K'))$. If some of the curves occurring as factors in $Z$ do not contain $K'$-rational points, then $Z(K')$ and hence $\hat{X}(K')$ are empty, and there is nothing to show. Otherwise, we can use a $K'$-point on each curve as a base-point for an embedding into its Jacobian variety, so that we can consider $\hat{X}$ as a subvariety of an abelian variety $A$ defined over $K'$. Note that $\hat{X}$ is of general type as well; in particular, $\hat{X}$ cannot be a translate of an abelian subvariety of $A$. Now Theorem 2.5 implies that $\hat{X}(K')$ is not Zariski dense in $\hat{X}$. It follows that $\pi(\hat{X}(K'))$ and therefore also its subset $X(K)$ are not Zariski dense in $X$.

If $\hat{X}$ does not contain any translate of an abelian subvariety of $A$ of positive dimension (which is equivalent to the assumption in (2)), then the finitely many translates in Theorem 2.5 are actually finitely many points, so that $\hat{X}(K')$ is finite. This implies that $X(K)$ is also finite.

Finally, Kawamata’s result 2.7 applies to $\hat{X}$, so if $\hat{Y}$ denotes the Zariski closure of the union of translates of positive dimensional abelian subvarieties of $A$ which are contained in $\hat{X}$, then $\hat{Y} \neq \hat{X}$ whence also $\pi(\hat{Y}) \neq X$. Note that the special subvariety $N$ of $X$ is exactly $\pi(\hat{Y})$. In particular, by what we have seen already, $\hat{X}(K') \setminus \hat{Y}(K')$ is finite. Therefore also $X(K) \setminus N(K) \subset \pi(\hat{X}(K') \setminus \hat{Y}(K'))$ is finite. Since $K$ can be replaced by any finite extension, the last claim follows.

Remark 2.9. For the purpose of actually determining $X(K)$, we assume in addition that the covering $\pi$ is geometrically Galois, so that $\hat{X}$ is an $X$-torsor under a
finite $K$-group scheme $G$ that we also assume to act on $Z$. ($G$ is allowed to have fixed points on $Z$, but not on $\hat{X}$.) This allows us to use the machinery of descent (see for example [Sko01]). There is then a finite collection of twists $\pi_\xi: \hat{X}_\xi \to X$ of the torsor $\hat{X} \to X$ such that $X(K) = \bigcup_\xi \pi_\xi(\hat{X}_\xi(K))$. This collection of twists can be taken to be those that are unramified outside the set of places of $K$ consisting of the archimedean places, the places dividing the order of $G$ and the places of bad reduction for $X$ or $\pi$.

Since $G$ also acts on $Z$ by assumption, we have $\hat{X}_\xi \subset Z_\xi$ for the corresponding twists of $Z$. The general form of such a twist is a principal homogeneous space for some abelian variety times a product of curves of higher genus or Weil restrictions of such curves over some finite extension of $K$ (the latter can occur when the action of $G$ on $Z$ permutes some of the curve factors). Write $Z_\xi = Z^{(1)}_\xi \times Z^{(2)}_\xi$, where $Z^{(1)}_\xi$ is the ‘abelian part’ and $Z^{(2)}_\xi$ is the ‘curve part’. By Faltings’ theorem, $Z^{(2)}_\xi$ has only finitely many $K$-rational points. Fixing such a point $P$, the fiber $X_{\xi,P}$ above $P$ of $\hat{X}_\xi \to Z^{(2)}_\xi$ is a subvariety of the principal homogeneous space $Z^{(1)}_\xi$.

So either $\hat{X}_{\xi,P}(K)$ is empty, or else we can consider $Z^{(1)}_\xi$ as an abelian variety, so that Faltings’ theorem applies to $\hat{X}_{\xi,P}$. This shows that $\hat{X}_{\xi,P}(K)$ is contained in a finite union of translates of abelian subvarieties of $Z^{(1)}_\xi$ that are contained in $\hat{X}_{\xi,P}$. Since there are only finitely many $P$, the corresponding statement holds for $\hat{X}_\xi$ as well.

The advantage of this variant is that it allows us to work with $K$-rational points on $\hat{X}$ and its twists, rather than with $K'$-rational points on $\hat{X}$ for a (usually rather large) extension $K'$ of $K$. So if we have a way of determining the translates of abelian subvarieties of positive dimension contained in $\hat{X}$ and also of finding the finitely many $K$-rational points outside these translates for each twist of $\hat{X}$, we can determine $X(K)$. We will pursue this approach when $X$ is a primary Burniat surface in the following sections.

In the same spirit we can give the following:

**Theorem 2.10.** Let $X$ be a smooth projective variety of general type over a number field $K$ which admits a finite étale covering $\pi: \hat{X} \to X$ such that the irregularity of $\hat{X}$ satisfies

$$q(\hat{X}) \geq \dim X + 1.$$

Then $X(K)$ is not Zariski dense in $X$.

If $\dim X = 2$, then $X$ contains only finitely many curves of geometric genus 0 or 1, and the set of $K$-rational points on $X$ outside these curves is finite.

**Proof.** Again it suffices to show that $\hat{X}(K')$ is not Zariski dense in $\hat{X}$ for some suitable finite extension $K'$ of $K$. We can assume that there is a point $x \in \hat{X}(K')$;
let \( \alpha: \hat{X} \to A \) be the Albanese morphism of \( \hat{X} \) that sends \( x \) to zero and note that \( \alpha \) is defined over \( K' \). Assume that \( \hat{X}(K') = \hat{X} \). Then \( \alpha(\hat{X}(K')) \subset A \) is a proper abelian subvariety of \( A \) of dimension \( \leq \dim X < \dim A \) by Faltings’ result. This is a contradiction, since \( \alpha(\hat{X}) \) spans \( A \).

If \( X \) is a surface, then we can use Lu’s or Kawamata’s result to deduce the finiteness of the set of low-genus curves on \( X \).

Theorem 2.8 applies to a generalization of Inoue’s construction of Burniat’s surfaces, the so-called \( \text{Inoue type varieties} \), which were recently introduced in [BC12], and which proved to be rather useful in the study of deformations in the large of surfaces of general type. In fact, it turned out that for Inoue type varieties under certain additional conditions one can show that any smooth variety homotopically equivalent to an Inoue type variety is in fact an Inoue type variety. This often allows to determine and describe the connected components of certain moduli spaces of surfaces of general type, since it implies that a family yields a closed subset in the moduli space. For details we refer to the original article [BC12].

We recall below the definition of a \( \text{classical Inoue type variety} \) as given in [BC12]. This is not sufficient for the results on moduli spaces, but is good enough for our study of rational points.

**Definition 2.11.** A complex projective variety \( X \) is called a \( \text{(classical) Inoue-type variety} \) if

1. \( \dim X \geq 2 \);
2. there is a finite group \( G \) and an unramified \( G \)-covering \( \hat{X} \to X \) (this means that \( X = \hat{X}/G \)), such that
3. \( \hat{X} \) is an ample divisor in
   \[
   Z := (A_1 \times \ldots \times A_r) \times (C_1 \times \ldots \times C_h),
   \]
   where each \( A_i \) is an abelian variety and each \( C_j \) is a curve of genus \( g_j \geq 2 \);
4. the action of \( G \) on \( \hat{X} \) yields a faithful action on the topological fundamental group \( \pi_1(\hat{X}) \);
5. the action of \( G \) on \( \hat{X} \) is induced by an action on \( Z \).

**Remark 2.12.** A classical Inoue type variety is of general type and if it is defined over a number field \( K \) (such that the \( G \)-action is also defined over \( K \)), then it satisfies the assumptions of Theorem 2.8 and also Remark 2.9.

### 3. Primary Burniat Surfaces

The so-called \( \text{Burniat surfaces} \) are several families of surfaces of general type with \( p_g = 0, \ K^2 = 6, 5, 4, 3, 2 \), first constructed by P. Burniat in [Bur66] as singular
bidouble covers (i.e., \((\mathbb{Z}/2\mathbb{Z})^2\) Galois covers) of the projective plane \(\mathbb{P}^2\) branched on a certain configuration of nine lines. Later, M. Inoue [Ino94] gave another construction of surfaces ‘closely related to Burniat’s surfaces’ with a different technique as \((\mathbb{Z}/2\mathbb{Z})^3\)-quotients of an invariant hypersurface of multi-degree \((2, 2, 2)\) in a product of three elliptic curves. In [BC11] it is shown that these two constructions give the same surfaces.

In fact, concerning statements about rational points on Burniat surfaces, Inoue’s construction is much more useful than the original construction of Burniat, as will be clear soon.

We briefly recall Burniat’s original construction of Burniat surfaces with \(K^2 = 6\), which were called primary Burniat surfaces in [BC11].

Consider three non collinear points \(p_1, p_2, p_3 \in \mathbb{P}^2\), which we take to be the co-ordinate points, and denote by \(Y := \hat{\mathbb{P}}^2(p_1, p_2, p_3)\) the blow-up of \(\mathbb{P}^2\) in \(p_1, p_2, p_3\). Then \(Y\) is a del Pezzo surface of degree 6 and it is the closure of the graph of the rational map

\[ \epsilon : \mathbb{P}^2 \rightarrow \mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1 \]

such that

\[ \epsilon(y_1 : y_2 : y_3) = ((y_2 : y_3), (y_3 : y_1), (y_1 : y_2)). \]

We denote by \(e_i\) the exceptional curve lying over \(p_i\) and by \(D_{i,1}\) the unique effective divisor in \(|l - e_i - e_{i+1}|\), i.e., the proper transform of the line \(y_{i-1} = 0\), side of the triangle joining the points \(p_i, p_{i+1}\). Here \(l\) denotes the total transform of a general line in \(\mathbb{P}^2\).

Consider on \(Y\) the divisors

\[ D_i = D_{i,1} + D_{i,2} + D_{i,3} + e_{i+2} \in |3l - 3e_i - e_{i+1} + e_{i+2}|, \]

where \(D_{i,j} \in |l - e_i|\), for \(j = 2, 3\), \(D_{i,j} \neq D_{i,1}\), is the proper transform of another line through \(p_i\) and \(D_{i,1} \in |l - e_i - e_{i+1}|\) is as above. Assume also that all the corresponding lines in \(\mathbb{P}^2\) are distinct, so that \(D := \sum_i D_i\) is a reduced divisor. In this description, the subscripts are understood as residue classes modulo 3.

If we define the divisor \(L_i := 3l - 2e_{i-1} - e_{i+1}\), then

\[ D_{i-1} + D_{i+1} \equiv 6l - 4e_{i-1} - 2e_{i+1} = 2L_i, \]

and we can consider the associated bidouble cover \(S \rightarrow Y\) branched on \(D\). Compare Figure 1.

Observe that \(S\) is nonsingular exactly when the divisor \(D\) does not have points of multiplicity 3 (there cannot be points of higher multiplicities).

**Definition 3.1.** A primary Burniat surface is a surface \(S\) as constructed above that is non-singular.
Remark 3.2. A primary Burniat surface $S$ is a minimal surface with $K_S$ ample. It has invariants $K_S^2 = 6$ and $p_g(S) = p_q(S) = 0$.

We now describe Inoue’s construction in detail, since we shall make extensive use of it. We pick three elliptic curves $E_1, E_2, E_3$, together with points $T_j \in E_j$ of order 2. On each $E_j$, we then have two commuting involutions, namely the translation by $T_j$ and the negation map. We now consider the group $\Gamma = \langle \gamma_1, \gamma_2, \gamma_3 \rangle$ of automorphisms of the product $E_1 \times E_2 \times E_3$ with
\[
\gamma_1: (P_1, P_2, P_3) \mapsto (P_1, P_2 + T_2, -P_3 + T_3) \\
\gamma_2: (P_1, P_2, P_3) \mapsto (-P_1 + T_1, P_2, P_3 + T_3) \\
\gamma_3: (P_1, P_2, P_3) \mapsto (P_1 + T_1, -P_2 + T_2, P_3).
\]
It can be checked that none of the $\gamma_j$ and none of the $\gamma_i \gamma_j$ (with $i \neq j$) have fixed points on $E_1 \times E_2 \times E_3$. The map $\gamma = \gamma_1 \gamma_2 \gamma_3$ is given by $(P_1, P_2, P_3) \mapsto (-P_1, -P_2, -P_3)$, so it has $4^3$ fixed points, namely the points $(P_1, P_2, P_3)$ such that $P_j$ is a 2-torsion point on $E_j$ for each $j$.

Now let $x_j$ be a function of degree 2 on $E_j$ that is invariant under the negation map and changes sign under translation by $T_j$. Then the product $x_1 x_2 x_3$ is invariant under $\Gamma$, and so the surface $X \subset E_1 \times E_2 \times E_3$ defined by $x_1 x_2 x_3 = c$ is also $\Gamma$-invariant.

Remark 3.3. It can be checked that $X$ is smooth unless it contains a fixed point of $\gamma$ or $c = 0$ [Ino94]. So as long as we avoid a finite set of values for $c$, the
surface \( X \) will be smooth and \( \Gamma \) acts on it without fixed points. We let \( S = X/\Gamma \) be the quotient. Then \( \pi: X \to S \) is an unramified covering that is Galois with Galois group \( \Gamma \). Both \( X \) and \( S \) are surfaces of general type.

In [BC11, Theorem 2.3] the following is proven:

**Theorem 3.4.** Primary Burniat surfaces are exactly the surfaces \( S = X/\Gamma \) as above such that \( \Gamma \) acts freely on \( X \).

**Remark 3.5.** It is now easy to see that primary Burniat surfaces are classical Inoue type varieties.

4. An explicit moduli space for primary Burniat surfaces

In [BC11, Theorem 4.1, Theorem 4.2] the following result is shown:

**Theorem 4.1.**

1. Let \( S \) be a smooth complex projective surface which is homotopically equivalent to a primary Burniat surface. Then \( S \) is a primary Burniat surface.
2. The subset \( M \) of the Gieseker moduli space corresponding to primary Burniat surfaces is an irreducible connected component, normal and rational of dimension 4.

In particular, this shows that if \( [S] \in M \), then \( S \) is in fact a primary Burniat surface, i.e., it can be obtained via Burniat’s and Inoue’s constructions.

Still, in [BC11] no explicit model of \( M \) is given. The goal of this section is to provide such an explicit moduli space based on Inoue’s construction. As a by-product, we obtain another proof of its rationality. We will also use our approach to classify the possible automorphism groups of primary Burniat surfaces, see Section 5 below. We work over \( \mathbb{C} \).

We first consider a curve \( E \) of genus 1 given as a double cover \( \pi_E: E \to \mathbb{P}^1 \) ramified in four points, together with a point \( T \in J \) of order 2, where \( J \) is the Jacobian elliptic curve of \( E \) (so that \( E \) is a principal homogeneous space for \( J \); more precisely, \( E \) is a 2-covering of \( J \) via \( P \mapsto P - \iota_E(P) \), where \( \iota_E \) is the involution on \( E \) induced by \( \pi_E \)). There is then a function \( x \) on \( \mathbb{P}^1 \), unique up to scaling and replacing \( x \) by \( 1/x \), such that \( x(\pi_E(P + T)) = -x(\pi_E(P)) \) for all \( P \in E \). (To see the uniqueness, fix a point \( Q \in E \) with \( Q - \iota_E(Q) = T \). Then the divisor of \( x \circ \pi_E \) must be \( \pm ((Q) + (\iota_E(Q)) - (Q + T') - (\iota_E(Q) + T')) \), where \( T' \neq T \) is another point of order 2.) As a double cover of \( \mathbb{P}^1 \) via \( x \), \( E \) is then given by an equation of the form \( y^2 = x^4 + ax^2 + b \). We fix the scaling of \( x \) up to a fourth root of unity by requiring \( b = 1 \). This fixes \( a \) up to a sign. So the moduli space of pairs \((E \to \mathbb{P}^1, T)\) as above is \( \mathbb{A}^1 \setminus \{4\} \), with the parameter for \( y^2 = x^4 + ax^2 + 1 \) being \( a^2 \). If we identify \( E \) with \( J \) by taking the origin to be one of the ramification
points of \( x \), then \( y \) changes sign under negation. In general, the fibers \( \{ P, P' \} \) of \( \pi_E: E \cong \mathbb{P} \to \mathbb{P}^1 \) are characterized by \( P + P' = Q \) for some point \( Q \in J \); then the automorphism \( \iota_E \) of \( E \) corresponding to changing the sign of \( y \) is given by \( P \mapsto Q - P \).

Consider the subvariety \( \mathcal{E} \) given by \( y^2 = x^4 + ax^2z^2 + z^4 \) in \( \mathbb{P}(1, 2, 1) \times (\mathbb{A}^1 \setminus \{ \pm 2 \}) \), where \( x, y, z \) are the coordinates of \( \mathbb{P}(1, 2, 1) \) and \( a \) is the coordinate on \( \mathbb{A}^1 \) (then \( x/z \) is the function denoted \( x \) in the previous paragraph). Then by the above, the group of automorphisms of \( \mathcal{E} \) that are compatible with the fibration over \( \mathbb{A}^1 \setminus \{ \pm 2 \} \) is generated by

\[
((x : y : z), a) \mapsto ((ix : y : z), -a) \quad \text{and} \quad ((x : y : z), a) \mapsto ((z : y : x), a).
\]

The fibers \( (E_a \to \mathbb{P}^1, T_a) \) and \( (E_b \to \mathbb{P}^1, T_b) \) over \( a \) and \( b \) are isomorphic (in the sense that there is an isomorphism \( E_a \to E_b \) that induces an automorphism of \( \mathbb{P}^1 \) and identifies \( T_a \) with \( T_b \)) if and only if \( b = \pm a \), and \( (E_a \to \mathbb{P}^1, T_a) \) has extra automorphisms if and only if \( a = 0 \).

We now use a similar approach to classify surfaces \( X \subset E_1 \times E_2 \times E_3 \) as in Inoue’s construction of primary Burniat surfaces. By the above, we can define \( X \) as a subvariety of \( E_1 \times E_2 \times E_3 \subset \mathbb{P}(1, 2, 1)^3 \) by equations

\[
\begin{align*}
y_1^2 &= x_1^4 + a_1x_1^2z_1^2 + z_1^4 \\
y_2^2 &= x_2^4 + a_2x_2^2z_2^2 + z_2^4 \\
y_3^2 &= x_3^4 + a_3x_3^2z_3^2 + z_3^4 \\
x_1x_2x_3 &= cz_1z_2z_3
\end{align*}
\]

(4.1)

with suitable parameters \( a_1, a_2, a_3 \neq \pm 2 \) and \( c \neq 0 \). Here \( x_j/z_j \) is the coordinate on \( E_j \) that changes sign under addition of \( T_j \) (denoted \( x \) above). We have to determine for which choices of the parameters \( (a_1, a_2, a_3, c) \) we obtain isomorphic surfaces \( X/\Gamma \).

Let \( A = (\mathbb{A}^1 \setminus \{ \pm 2 \})^3 \times (\mathbb{A}^1 \setminus \{ 0 \}) \) and consider \( \mathcal{X} \subset \mathbb{P}(1, 2, 1)^3 \times A \) as given by equations (4.1), where \( x_j, y_j, z_j \) are the coordinates on the three factors \( \mathbb{P}(1, 2, 1) \) (for \( j = 1, 2, 3 \)) and \( a_1, a_2, a_3, c \) are the coordinates on \( A \). Then the group of automorphisms of \( \mathbb{P}(1, 2, 1)^3 \times A \) that fix \( \mathcal{X} \) and are compatible with the fibration over \( A \) is generated by the elements that map the point

\[
((x_1 : y_1 : z_1), (x_2 : y_2 : z_2), (x_3, y_3, z_3), (a_1, a_2, a_3, c))
\]
to the point given below.

\[\begin{align*}
\rho_1 & : \left( i x_1 : y_1 : z_1 \right), \quad \left( x_2 : y_2 : z_2 \right), \quad \left( x_3, y_3, z_3 \right), \quad \left( -a_1, a_2, a_3, ic \right) \\
\rho_2 & : \left( x_1 : y_1 : z_1 \right), \quad \left( i x_2 : y_2 : z_2 \right), \quad \left( x_3, y_3, z_3 \right), \quad \left( a_1, -a_2, a_3, ic \right) \\
\rho_3 & : \left( x_1 : y_1 : z_1 \right), \quad \left( x_2 : y_2 : z_2 \right), \quad \left( i x_3, y_3, z_3 \right), \quad \left( a_1, a_2, -a_3, ic \right) \\
\gamma' & : \left( x_1 : -y_1 : z_1 \right), \quad \left( x_2 : y_2 : z_2 \right), \quad \left( x_3, y_3, z_3 \right), \quad \left( a_1, a_2, a_3, c \right) \\
\gamma'' & : \left( x_1 : y_1 : z_1 \right), \quad \left( x_2 : -y_2 : z_2 \right), \quad \left( x_3, y_3, z_3 \right), \quad \left( a_1, a_2, a_3, c \right) \\
\gamma_3 & : \left( x_1 : y_1 : z_1 \right), \quad \left( x_2 : y_2 : z_2 \right), \quad \left( x_3, -y_3, z_3 \right), \quad \left( a_1, a_2, a_3, c \right) \\
\tau & : \left( z_1 : y_1 : x_1 \right), \quad \left( z_2 : y_2 : x_2 \right), \quad \left( z_3, y_3, x_3 \right), \quad \left( a_1, a_2, a_3, 1/c \right) \\
\sigma & : \left( x_2 : y_2 : z_2 \right), \quad \left( x_3 : y_3 : z_3 \right), \quad \left( x_1, y_1, z_1 \right), \quad \left( a_2, a_3, a_1, c \right) \\
\tau' & : \left( x_2 : y_2 : z_1 \right), \quad \left( x_1 : y_1 : z_2 \right), \quad \left( x_3, y_3, z_3 \right), \quad \left( a_2, a_3, a_1, c \right)
\end{align*}\]

Note that \( \Gamma = \langle \rho_1^2 \rho_2^2 \gamma'_1, \rho_2^2 \gamma_3^2 \rangle \) fixes \( \mathcal{X} \) fiber-wise. Since we are interested in the quotients of the fibers by this action, we restrict to the subgroup consisting of elements normalizing \( \Gamma \). This means that we exclude \( \tau' \).

So let \( \tilde{\Gamma} = \langle \rho_1, \rho_2, \rho_3, \gamma'_1, \gamma'_2, \gamma'_3, \tau, \sigma \rangle \). The first six elements generate an abelian normal subgroup isomorphic to \((\mathbb{Z}/4\mathbb{Z})^3 \times (\mathbb{Z}/2\mathbb{Z})^2\) on which \(\tau\) acts by negation and \(\sigma\) acts by cyclically permuting the factors in both \((\mathbb{Z}/4\mathbb{Z})^3\) and \((\mathbb{Z}/2\mathbb{Z})^3\). In particular, \(\tilde{\Gamma}\) has order \(4^3 \cdot 2^3 \cdot 2 \cdot 3 = 2^{10} \cdot 3\). We note that the kernel of the natural homomorphism \( \Gamma \rightarrow \text{Aut}(A) \) is \( \Gamma_0 := \langle \Gamma, \gamma'_1, \gamma'_2 \rangle \) (we also have \( \gamma'_3 = \gamma \gamma'_1 \gamma'_2 \in \Gamma_0 \)).

So on the quotient \( S \) of every fiber \( X \) by \( \Gamma \), we have an action of \( \tilde{\Gamma}_0/\Gamma \), and the quotient of \( S \) by this action is the del Pezzo surface \( \tilde{Y} \) in Burniat’s construction.

The image \( \tilde{\Gamma}_A \) of \( \tilde{\Gamma} \) in \( \text{Aut}(A) \) is generated by

\[\begin{align*}
\tilde{\rho}_1 & : (a_1, a_2, a_3, c) \mapsto (-a_1, a_2, a_3, ic) \\
\tilde{\rho}_2 & : (a_1, a_2, a_3, c) \mapsto (a_1, -a_2, a_3, ic) \\
\tilde{\rho}_3 & : (a_1, a_2, a_3, c) \mapsto (a_1, a_2, -a_3, ic) \\
\tilde{\tau} & : (a_1, a_2, a_3, c) \mapsto (a_1, a_2, a_3, 1/c) \\
\tilde{\sigma} & : (a_1, a_2, a_3, c) \mapsto (a_2, a_3, a_1, c)
\end{align*}\]

Note that \( \zeta := \tilde{\rho}_1^2 = \tilde{\rho}_2^2 = \tilde{\rho}_3^2 \) just changes the sign of \( c \). The order of \( \tilde{\Gamma}_A \) is 96. There are twenty conjugacy classes. The table below gives a representative element, its order and the size of each class.

Given a primary Burniat surface $S$, the $\mathbb{Z}/2\mathbb{Z}$-cover $\pi: X \to S$ with $X \subset E_1 \times E_2 \times E_3$ is uniquely determined up to isomorphism as the unramified covering corresponding to the unique normal abelian subgroup of $\pi_1(S)$ such that the quotient is $(\mathbb{Z}/2\mathbb{Z})^3$. It follows that the (coarse) moduli space $M$ of primary Burniat surfaces is $A'/\tilde{\Gamma}_A$, where $A'$ is the open subset of $A$ over which the fibers of $X$ do not pass through a fixed point of $\gamma$. We determine the invariants for this group action. We have the normal subgroup $\langle \zeta, \tau \rangle \cong (\mathbb{Z}/2\mathbb{Z})^2$ that fixes $(a_1, a_2, a_3)$ and has orbit $A^+$. The invariants for this action are $a_1, a_2, a_3$ and $v := c^2 + 1/c^2$. The action of $\tilde{\rho}_j$ on these invariants is given by changing the signs of $a_j$ and $v'$, so the invariants of the action by the group generated by the $\tilde{\rho}_j$ and $\tilde{\tau}$ are $a_1^2, a_2^2, a_3^2, v := v'^2$ and $w := a_1a_2a_3v'$. Finally, $\tilde{\sigma}$ fixes $v$ and $w$ and permutes $a_1^2, a_2^2, a_3^2$ cyclically. So the invariants of the action of $\tilde{\Gamma}_A$ are the elementary symmetric polynomials in the $a_j^2$, namely

$$u_1 = a_1^2 + a_2^2 + a_3^2, \quad u_2 = a_1^2a_2^2 + a_2^2a_3^2 + a_3^2a_1^2, \quad u_3 = a_1^2a_2^2a_3^2,$$

together with $d = (a_1^2 - a_2^2)(a_2^2 - a_3^2)(a_3^2 - a_1^2)$ and $v, w$.

This exhibits the moduli space $M$ as a bidouble cover of an open subset of $A^4$ (with coordinates $u_1, u_2, u_3, v$) as follows.

**Theorem 4.2.** The moduli space $M$ of primary Burniat surfaces is the open subset of $A^6$ defined by the following equations and inequalities.

$$-4u_1^3u_3 + u_1^2u_2^2 + 18u_1u_2u_3 - 4u_2^3 - 27u_3^2 = d^2$$

$$u_3v = w^2$$

$$(v - u_1)^2 + u_2(v - 4) + u_3 + (u_1 + v - 8)w \neq 0$$

$$64 - 16u_1 + 4u_2 - u_3 \neq 0$$

**Proof.** This follows from the discussion above. Note that the expression on the left hand side of the first equation is the discriminant of $X^3 - u_1X^2 + u_2X - u_3$. The first inequality is equivalent to the non-vanishing of the discriminant of $X$ as defined in Section 7 below and the second inequality encodes the non-singularity of the curves $y_j^2 = x_j^3 + a_jx_j^2z_j^2 + z_j^4$ (which is equivalent to $a_j^2 \neq 4$).

**Corollary 4.3.** $M$ is rational.

**Proof.** First note that $M$ is birational to $A^1$ times the double cover of $A^3$ given by the first equation (we can eliminate $v$ using the second equation, and then $w$ is a free variable). The first equation is equivalent to

$$4(3u_2 - u_1^2)^3 = (27u_3 + 2u_1^3 - 9u_1u_2)^2 + 27d^2.$$

By a coordinate change, we reduce to $A^2$ times the rational surface given by $x^3 + y^2 + z^2 = 0$. \qed
5. Automorphism groups of primary Burniat surfaces

We now consider the group of automorphisms of a primary Burniat surface $S$. Since the covering $\pi: X \to S$ is unique, every automorphism of $S$ lifts to an element of $\tilde{\Gamma}$ fixing $X$. We have already seen that $\text{Aut}(S)$ always contains $\bar{\Gamma}_0 := \tilde{\Gamma}_0/\Gamma \cong (\mathbb{Z}/2\mathbb{Z})^2$; since $\tilde{\Gamma}_0$ is normal in $\tilde{\Gamma}$, this is a normal subgroup of $\text{Aut}(S)$.

Additional automorphisms of $X$ correspond to elements of $\tilde{\Gamma}$ that fix the parameters $(a_1, a_2, a_3, c)$. There are the following possibilities for such elements modulo $\bar{\Gamma}_0$. We give their images in $\tilde{\Gamma}_A$, up to conjugation. Note that $\zeta, \bar{\rho}_1, \bar{\rho}_2 \bar{\rho}_3, \bar{\rho}_1 \bar{\rho}_2, \zeta \bar{\sigma}, \bar{\rho}_1 \bar{\sigma}, \zeta \bar{\sigma}^2, \bar{\rho}_1 \bar{\sigma}^2$ map $c$ to $\pm i c$ or $-c$ and cannot fix any $c \neq 0$. Also, $\bar{\rho}_1 \bar{\rho}_2 \bar{\rho}_3 \bar{\tau}$ can only fix $(a_1, a_2, a_3, c)$ when $a_1 = a_2 = a_3 = 0$ and $c^4 + 1 = 0$, which is excluded (it corresponds to a singular $X$).

(i) $\bar{\tau}$, corresponding to $c = 1/c$; this is $v = 4$ on $M$.
Then $\text{Aut}(S)$ acquires an extra involution $\tau'$ that commutes with $\bar{\Gamma}_0$. We write $M_1$ for the corresponding subvariety of $M$.

(ii) $\bar{\rho}_1 \bar{\rho}_2^{-1}$, corresponding to $a_1 = a_2 = 0$; this is $u_2 = u_3 = 0$ on $M$, which implies $d = w = 0$.
Then $\text{Aut}(S)$ acquires an element $\rho'$ of order 4 that commutes with $\bar{\Gamma}_0$ and whose square is in $\bar{\Gamma}_0$. We write $M_2$ for the corresponding subvariety of $M$.

(iii) $\bar{\rho}_1 \bar{\tau}$, corresponding to $a_1 = 0$ and $c = i/c$; this is $u_3 = v = 0$ on $M$, which implies $w = 0$.
Then $\text{Aut}(S)$ acquires an extra involution $\tau''$ that commutes with $\bar{\Gamma}_0$. We write $M_3$ for the corresponding subvariety of $M$.

(iv) $\bar{\sigma}$, corresponding to $a_1 = a_2 = a_3$; this is $d = 0, u_1^2 = 3u_2, u_1 u_2 = 9u_3$ on $M$.
Then $\text{Aut}(S)$ acquires an extra element $\sigma'$ of order 3 that acts non-trivially on $\bar{\Gamma}_0$. The subgroup of $\text{Aut}(S)$ generated by $\bar{\Gamma}_0$ and the additional automorphism is isomorphic to the alternating group $A_4$. We write $M_4$ for the corresponding subvariety of $M$.

By considering the action on $(a_1, a_2, a_3, c)$, it can be checked that elements of other conjugacy classes can only be present when we are in one of the four cases (i)–(iv) above. More precisely, of the 14 subgroups up to conjugacy that do not contain one of the ‘forbidden’ elements given above, four cannot occur, since the action implies that there is actually a larger group present. The ten remaining groups correspond to those given below.
Note that $M_1 \cap M_3 = M_3 \cap M_4 = \emptyset$. We obtain the following stratification of $M$.

The leftmost column gives the dimension.

<table>
<thead>
<tr>
<th>Stratum</th>
<th>$\text{Aut}(S)$</th>
<th>$\text{Aut}(S)/\bar{\Gamma}'$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$M$</td>
<td>$C_2^2$</td>
<td>$C_1$</td>
</tr>
<tr>
<td>$M_1$</td>
<td>$C_2^3$</td>
<td>$C_2$</td>
</tr>
<tr>
<td>$M_2$</td>
<td>$C_2 \times C_4$</td>
<td>$C_2$</td>
</tr>
<tr>
<td>$M_3$</td>
<td>$C_3^2$</td>
<td>$C_2$</td>
</tr>
<tr>
<td>$M_4$</td>
<td>$A_4$</td>
<td>$C_3$</td>
</tr>
<tr>
<td>$M_1 \cap M_2$</td>
<td>$C_2 \times D_4$</td>
<td>$C_2^2$</td>
</tr>
<tr>
<td>$M_1 \cap M_4$</td>
<td>$C_2 \times A_4$</td>
<td>$C_6$</td>
</tr>
<tr>
<td>$M_2 \cap M_3$</td>
<td>$C_2 \times D_4$</td>
<td>$C_2^2$</td>
</tr>
<tr>
<td>$M_2 \cap M_4$</td>
<td>$(C_4 \wr C_3)/C_4$</td>
<td>$A_4$</td>
</tr>
<tr>
<td>$M_1 \cap M_2 \cap M_4$</td>
<td>$(C_4 \wr C_3)/C_4 \rtimes C_2$</td>
<td>$A_4 \times C_2$</td>
</tr>
</tbody>
</table>

Note that $M_1 \cap M_2 \cap M_4$ is the single point $(u_1, u_2, u_3, d, v, w) = (0, 0, 0, 0, 4, 0)$, which is represented by $(a_1, a_2, a_3, c) = (0, 0, 0, 1)$.

The following table specifies $\text{Aut}(S)$ and $\text{Aut}(S)/\bar{\Gamma}'$ for the various strata. We write $C_n$ for a cyclic group of order $n$ and $D_4$ for the dihedral group of order 8. For a group $G$, $(G \wr C_3)/G$ denotes the wreath product $G^3 \rtimes C_3$ divided by the diagonal image of $G$ in the normal subgroup $G^3$. Note that $A_4 \cong (C_2 \wr C_3)/C_2$.

The semidirect product $(C_4 \wr C_3)/C_4 \rtimes C_2$ in the last line is such that the nontrivial element of $C_2$ (which is $\tau'$) acts on $(C_4 \wr C_3)/C_4$ by simultaneously inverting the elements in the $C_4$ components. The table can be checked by observing that $\tau'^2 = \tau''^2 = 1$, $\rho'^2 \in \bar{\Gamma}$, $\rho'^4 = 1$, $\tau' \rho' = \rho'^{-1} \tau'$, $\tau'' \rho' = \rho'^{-1} \tau''$, $\tau' \sigma' = \sigma' \tau'$, $(\rho' \sigma')^3 = 1$, and $\tau'$, $\rho'$, $\tau''$ commute with $\bar{\Gamma}_0$, whereas $\sigma'$ acts non-trivially on it.
6. Low genus curves on primary Burniat surfaces

We now study the set of curves of geometric genus 0 or 1 on a primary Burniat surface $S$. This is more easily done using Inoue’s construction of $S$ as an étale quotient of a hypersurface $X$ in a product $E_1 \times E_2 \times E_3$ of three elliptic curves. Since $X$ does not contain rational curves, the same is true of $S$. So it remains to find the curves of geometric genus 1 on $S$. Such curves are images of smooth curves of genus 1 contained in $X$ under the quotient map $\pi: X \to S$, so we need to classify these.

Let $E \subset X$ be a curve of genus 1. The three projections of $E_1 \times E_2 \times E_3$ give us three morphisms $\psi_j: E \to X \to E_j$, which must be translations followed by isogenies or constant. There are three cases. Note that at least one of these morphisms must be non-constant.

6.1. Two of the $\psi_j$ are constant. Say $\psi_2$ and $\psi_3$ are constant, with values $(\xi_2: \eta_2: \zeta_2)$ and $(\xi_3: \eta_3: \zeta_3)$. If $\xi_2\xi_3 \neq 0$, this would force $x_1 = c(\zeta_2\zeta_3/\xi_2\xi_3)z_1$, and $\psi_1$ would have to be constant as well. So $\xi_2 = 0$ (say). Since $c \neq 0$, we must then have $\zeta_3 = 0$. This gives two choices for the image of $\psi_2$ and two choices for the image of $\psi_3$; by interchanging the roles of $\xi$ and $\zeta$, we obtain four further choices. This gives rise to eight copies of $E_1$ in $X$ that are pairwise disjoint. Under the action of $\Gamma$, they form two orbits of size four, so on $S$ we obtain two copies of $E_1/\langle T_1 \rangle$. In the same way, we have two copies each of $E_2/\langle T_2 \rangle$ and of $E_3/\langle T_3 \rangle$. These six smooth curves of genus 1 are arranged in the form of a hexagon, with the two images of $E_j$ corresponding two opposite sides. In Burniat’s original construction, these curves are obtained as preimages of the three lines joining the three points that are blown up and the three exceptional divisors obtained from blowing up the points.

Definition 6.1. We call these six curves the curves at infinity on $S$.

These six curves are arranged in form of a hexagon, see Figure 2.

6.2. Exactly one of the $\psi_j$ is constant. Say $\psi_1$ is constant. The fibers of any of the projections $X \to E_j$ are curves of genus 5, which are generically smooth. Taking $j = 1$, we get explicit equations for the fiber in the form

$$y_2^2 = x_2^4 + a_2 x_2^2 z_2^2 + z_2^4$$
$$y_3^2 = x_3^4 + a_3 x_3^2 z_3^2 + z_3^4$$
$$\xi_1 x_2 x_3 = c\zeta_1 z_2 z_3$$

where $(\xi_1: \eta_1: \zeta_1) \in E_1$ is the point we take the fiber over. If $\xi_1 = 0$ or $\zeta_1 = 0$, then the fiber splits into two of the curves described in Section 6.1 (taken twice).
Otherwise, the third equation is equivalent to \((x_3 : z_3) = (c\zeta_1 z_2 : \xi_1 x_2)\). Using this in the second equation, we can reduce to the pair
\[
\begin{align*}
y_2^2 &= x_2^4 + a_2 x_2^2 z_2^2 + z_2^4 \\
y_3^2 &= \xi_1^4 x_2^4 + a_3 c^2 \xi_1^2 \zeta_1^2 x_2^2 z_2^2 + c^4 \zeta_1^4 z_2^4
\end{align*}
\]
of equations describing the fiber as a bidouble cover of \(\mathbb{P}^1\).

The fiber degenerates if and only if the two quartic forms in \((x_2, z_2)\) have common roots. This occurs exactly when their resultant
\[
R = \left(c^4 \xi_1^4 \zeta_1^4 (a_2^2 + a_3^2) - c^2 \xi_1^2 \zeta_1^2 (\xi_1^4 + c^4 \zeta_1^4) a_2 a_3 + (\xi_1^4 - c^4 \zeta_1^4)^2\right)^2
\]
vanishes. Writing \(\xi = \xi_1/(c\zeta_1)\), this is equivalent to
\[
\xi^8 - a_2 a_3 \xi^6 + (a_2^2 + a_3^2 - 2) \xi^4 - 2 a_2 a_3 \xi^2 + 1 = 0.
\]
So generically (in terms of \(a_2\) and \(a_3\)) this occurs for eight values of \(\xi\), and then the two quartic forms have one pair of common roots, leading to a fiber that is a curve of geometric genus 3 with two nodes. But it is also possible that both quartics are proportional. This happens if and only if \(a_2 = \pm a_3\) (and \(\xi = \pm 1\) if \(a_2 = a_3\), \(\xi = \pm i\) if \(a_2 = -a_3\)). In that case, the fiber splits into two curves isomorphic to \(E_2\) and \(E_3\) that meet transversally in the four points where \(y_2 = y_3 = 0\). The two values of \(\xi\) give rise to four fibers (note that the point \((\xi_1 : \eta_1 : \zeta_1)\) on \(E_1\) cannot have \(\eta_1 = 0\), since then \(X\) would contain a fixed point of \(\gamma\)), together containing eight copies of \(E_2\) (or \(E_3\)). The action of \(\Gamma\) permutes these eight curves transitively. The stabilizer of a fiber swaps its two components and interchanges the four intersection points in pairs, so that the image of either component on \(S\)
is a curve of geometric genus 1 with two nodes. Note that the existence of these curves does not depend on the value of $c$ (as long as $X$ is smooth).

If both $a_2 = a_3$ and $a_2 = -a_3$, so that $a_2 = a_3 = 0$ (which means that the curves have complex multiplication by $\mathbb{Z}[i]$), then we obtain two orbits of this kind, leading to two curves of geometric genus 1 on $S$. So in the extreme case $a_1 = a_2 = a_3 = 0$, we obtain the maximal number of six such curves on $S$. This situation is shown in Figure 3 in terms of the images of the curves in $\mathbb{P}^2$ with respect to Burniat’s construction. In general, the table below gives the number of these curves (the subscripts are understood up to cyclic permutation).

<table>
<thead>
<tr>

</tbody>
</table>

Note that the fibrations of $X$ given by the projections to the $E_j$ are stable under $\Gamma$. They induce fibrations $S \to \mathbb{P}^1$ with fibers of genus 3. In Burniat’s construction, these fibrations are obtained by pulling back the pencils of lines through one of the three points on $\mathbb{P}^2$ that are blown up. Using this, it is easy to see that the fibers in $X$ over the ramification points of $E_j \to \mathbb{P}^1$ map to smooth curves of genus 2 on $S$ (taken twice).

Figure 3. Six curves of type I. They are the preimages in $S$ of the six black lines. Here two of the blown-up points are at infinity.
Definition 6.2. We call the curves of geometric genus 1 on $S$ arising in this way curves of type I.

See the left part of Figure 5 for how a curve of type I sits inside $S$.

We write $N_1$ for the subset of $M$ given by $d = 0$, which corresponds to surfaces admitting curves of type I.

6.3. No $\psi_j$ is constant. We abuse notation slightly and write $x_j$ for the rational function $x_j/\psi_j$ on $E_j$ (and $X$). If $E \subset X$ is an elliptic curve and all $\psi_j$ are non-constant, then each $\psi_j$ has the form $\psi_j(P) = \varphi_j(P - Q_j)$, where $Q_j \in E$ is some point and $\varphi_j : E \to E_j$ is an isogeny. The condition that $E$ is contained in $X$ then means that

$$(x_1 \circ \varphi_1) \cdot (x_2 \circ \varphi_2) \cdot (x_3 \circ \varphi_3) = c.$$ 

In particular, we must have

$$\tau_{Q_1} \varphi_1^* (\text{div}(x_1)) + \tau_{Q_2} \varphi_2^* (\text{div}(x_2)) + \tau_{Q_3} \varphi_3^* (\text{div}(x_3)) = \text{div}(x_1 \circ \varphi_1) + \text{div}(x_2 \circ \varphi_2) + \text{div}(x_3 \circ \varphi_3) = 0,$$

where $\tau_Q$ denotes translation by $Q$.

It can be checked that the fours points above 0 and $\infty$ on $E_j$ form a principal homogeneous space for the 2-torsion subgroup $E_j[2]$. So, taking the coefficients mod 2, $\text{div}(x_j) \equiv [2]^*(P_j)$ for some point $P_j \in E_j$, where $[2]$ denotes the multiplication-by-2 map. The relation above then implies that

$$\tau_{Q'_1} [2]^* K_1 + \tau_{Q'_2} [2]^* K_2 + \tau_{Q'_3} [2]^* K_3 \equiv 0 \mod 2$$

with suitable points $Q'_j \in E$, where $K_j$ denotes the formal sum of the points in the kernel of $\varphi_j$. This in turn is equivalent to

$$K_1 + \tau_{2Q'_3 - 2Q'_1} K_2 + \tau_{2Q'_3 - 2Q'_1} K_3 \equiv 0 \mod 2.$$

In down-to-earth terms, this means that there are cosets of $\ker(\varphi_1)$ (which we can take to be $\ker(\varphi_1)$ itself), $\ker(\varphi_2)$ and $\ker(\varphi_3)$ such that every point of $E$ is contained in either none or exactly two of these cosets. Since $0 \in \ker(\varphi_1)$, exactly one of the two other cosets must contain 0; we can assume that this is $\ker(\varphi_2)$. Then the condition is that the symmetric difference of $\ker(\varphi_1)$ and $\ker(\varphi_2)$ must be a coset of $\ker(\varphi_3)$.

Since $E \subset X \subset E_1 \times E_2 \times E_3$, the intersection of all three kernels is trivial. Now assume that $G = \ker(\varphi_1) \cap \ker(\varphi_2) \neq \{0\}$. Then the symmetric difference of $\ker(\varphi_1)$ and $\ker(\varphi_2)$ is a union of cosets of $G$, which implies that $G \subset \ker(\varphi_3)$, a contradiction. So $\ker(\varphi_1) \cap \ker(\varphi_2) = \{0\}$ (and the same holds for the other two intersections) and hence the symmetric difference is $\ker(\varphi_1) \cup \ker(\varphi_2) \setminus \{0\}$. Now if $\# \ker(\varphi_1) > 2$, then this symmetric difference contains two elements of $\ker(\varphi_1)$ whose difference then must be in $\ker(\varphi_1) \cap \ker(\varphi_3)$, which is impossible. So
# ker(ϕ₁) ≤ 2 and similarly # ker(ϕ₂) ≤ 2. On the other hand, the kernels cannot both be trivial (then the symmetric difference would be empty and could not be a coset). So, up to cyclic permutation of the subscripts, this leaves two possible scenarios:

1. # ker(ϕ₁) = 2 and ker(ϕ₂) and ker(ϕ₃) are trivial;
2. ker(ϕ₁), ker(ϕ₂) and ker(ϕ₃) are the three subgroups of order 2 of E.

We now have to check whether and how these possibilities can indeed be realized.

![Figure 4](image_url)

**Figure 4.** The possible arrangements of the divisors of \(x_1 \circ ψ_1\) (red), \(x_2 \circ ψ_1\) (green) and \(x_3 \circ ψ_3\) (blue). On the left is Scenario (1), on the right Scenario (2). ● denotes a zero, o a pole of \(x_j \circ ψ_j\).

In Scenario (1), \(E\), \(E_2\) and \(E_3\) are isomorphic. We identify \(E_2\) and \(E_3\) with \(E\) via the isomorphisms \(ψ_2\) and \(ψ_3\). The points above 0 and ∞ on \(E_2\) and \(E_3\) then have to be distinct, and the two corresponding cosets of \(E[2]\) must differ by a point \(Q\) of order 4 such that ker(ϕ₁) = \{0, 2Q\}. In div\((x_1 \circ ψ_1)\), points differing by 2\(Q\) then have the same sign, which implies that \(T_2 = T_3 = 2Q := T\) (recall that \(T_j\) is the point of order 2 on \(E_j\) such that adding \(T_j\) changes the sign of \(x_j\)). Let \(T' \in E\) be a point of order 2 with \(T' \neq T\). Then we can realize this scenario by taking

\[
ψ_1 : E \to E_1 := E/(T), \quad ψ_2 = \text{id}_E : E \to E_2 := E, \quad ψ_3 = \text{id}_E : E \to E_3 := E
\]

and choosing the \(x_j\) such that

\[
\begin{align*}
\text{div}(x_1 \circ ψ_1) &= (O) + (Q) + (T) + (−Q) − (T') − (T' + Q) − (T' + T) − (T' − Q), \\
\text{div}(x_2 \circ ψ_2) &= (T') + (T + T') − (O) − (T), \\
\text{div}(x_3 \circ ψ_3) &= (T' + Q) + (T' − Q) − (Q) − (−Q).
\end{align*}
\]

See the left part of Figure 4.

More concretely, let

\[
E : y^2 = x(x - 1)(x - λ^2),
\]
which has a point $Q = (\xi, \eta) = (\lambda, i\lambda(1 - \lambda))$ of order 4 such that $T = 2Q = (0, 0)$. Then $E_1 = E/\langle T \rangle$ is

$$E_1 : y^2 = (x - 2\lambda)(x + 2\lambda)(x - (1 + \lambda^2));$$

with

$$x_1 = \frac{(1 + \lambda)y}{(x + 2\lambda)(x - (1 + \lambda^2))} \quad \text{and} \quad y_1 = \frac{x^2 - 4\lambda x + 4\lambda(1 - \lambda + \lambda^2)}{(x + 2\lambda)(x - (1 + \lambda^2))}$$

this gives the equation

$$y_1^2 = x_1^4 + 2\frac{1 - 6\lambda + \lambda^2}{(1 + \lambda)^2}x_1^2 + 1$$

for $E_1$. On $E_2 = E = E_3$, we take

$$x_2 = \frac{1}{\sqrt{1 - \lambda^2}} \frac{y}{x} \quad \text{and} \quad x_3 = \sqrt{-\frac{1 - \lambda}{1 + \lambda}} \frac{x + \lambda}{x - \lambda}.$$

This gives the following equations for $E_2$ and $E_3$:

$$y_2^2 = x_2^4 + 2\frac{1 + \lambda^2}{1 - \lambda^2}x_2^2 + 1, \quad y_3^2 = x_3^4 + 2\frac{1 + \lambda^2}{1 - \lambda^2}x_3^2 + 1$$

with $y_2 = 1/(1 - \lambda^2) \cdot (x - \lambda^2/x)$ and $y_3 = 4i\lambda/(1 + \lambda) \cdot y/(x - \lambda)^2$. Since the isogeny $E \to E_1$ is given by $(x, y) \mapsto (x + \lambda^2/x, (1 - \lambda^2/x^2)y)$, we get indeed that

$$(x_1 \circ \psi_1)x_2x_3 = \frac{(1 + \lambda)(x - \lambda)y}{(x + \lambda)(x - 1)(x - \lambda^2)} \cdot \frac{1}{\sqrt{1 - \lambda^2}} \frac{y}{x} \cdot \sqrt{-\frac{1 - \lambda}{1 + \lambda}} \frac{x + \lambda}{x - \lambda}$$

$$= \pm i \frac{y^2}{x(x - 1)(x - \lambda^2)} = \pm i$$

is constant. (The sign depends on the choice of the two square roots.)

We can read off the intersection multiplicities with the elliptic curves ‘at infinity’ of $X$ from the divisors of the functions $x_j \circ \psi_j$: a point that occurs positively in $\text{div}(x_j \circ \psi_j)$ and negatively in $\text{div}(x_k \circ \psi_k)$ contributes one (transversal) intersection of $E$ with a curve in $X \cap \{x_j = z_k = 0\}$ and therefore also contributes one to the intersection multiplicity of $\pi(E)$ with the image of these curves on $S$. In our case, we obtain intersection multiplicity 2 for

$$x_1 = z_2 = 0, \quad x_1 = z_3 = 0, \quad z_1 = x_2 = 0, \quad z_1 = x_3 = 0,$$

and no intersection for $x_2 = z_3 = 0$ and for $z_2 = x_3 = 0$.

The $\Gamma$-orbit of such a curve has size 8. In terms of points $P$ on $E$, the action of $\Gamma$ on $E$ is as follows. We write $\psi = \psi_1$. Note that the automorphisms that negate
the \( y \)-coordinate are given, respectively, by \( P \mapsto \psi(Q) - P \), \( P \mapsto T - P \), \( P \mapsto -P \) on \( E_1, E_2, E_3 \).

</table>

In the column labeled ‘intersection’, we list the points \( P \in E \) that lie on the corresponding translate of \( E \). The entries show that each curve in the orbit intersects two other curves in the orbit in four points each, which are on some of the curves at infinity, and intersects another curve in eight points. These intersection points are swapped in pairs by the element of \( \Gamma \) that interchanges the two intersecting curves. So the image of this orbit in \( S \) is a curve of geometric genus 1 with eight nodes (and hence arithmetic genus 9). Its image on \( \mathbb{P}^2 \) is a conic passing through exactly two of the blown-up points, which at these points is tangent to one of the lines in the branch locus, intersects the two lines joining the two points with the third at an intersection point with another branch line and is tangent to two further branch lines; see Figure 6, Left. It can be checked that there can be at most one such conic through a given pair of the points unless the two corresponding \( E_j \) have \( a_j = 0 \). In this case, there are either none or two such conics, see Figure 6, Right.
(When $a_2 = a_3 = 0$, say, then $(x_1, y_1, x_2, y_2, x_3, y_3) \mapsto (-x_1, y_1, ix_2, y_2, ix_3, y_3)$ is an additional automorphism of $X$, which descends to an automorphism of $S$ that swaps the two curves.)

If such a curve is to exist on $S$, two of the $a_j$ must agree up to sign, and the third must satisfy a relation with the first two, which is (for $a_2 = a_3$ as above)

$$\left(a_1 - 2(a_2^2 - 3)\right)^2 = 4a_2^2(a_2^2 - 4).$$

In addition, we must have $c^2 = -1$ if $a_2 = a_3 \neq 0$, and $c^4 = 1$ otherwise. Of course, we can replace $a_1$ by $-a_1$; then $c^2 = 1$ if $a_2 = a_3 \neq 0$. This translates into $(u_1, u_2, u_3, w)$ being on a curve (and $d = 0, v = 4$).

The locus in $M$ of points whose associated surfaces contain curves of type II is a smooth rational curve of degree 6. One possible parameterization is

\[
\begin{align*}
  u_1 &= -2\frac{t^3 - 4t^2 - 7t - 8}{t^2} \\
  u_2 &= \frac{(t - 1)^2(t^5 - 10t^2 - 31t - 32)}{t^3} \\
  u_3 &= 4\frac{(t - 1)^4(t + 2)^2}{t^4} \\
  d &= 0 \\
  v &= 4 \\
  w &= -4\frac{(t - 1)^2(t + 2)}{t^2}
\end{align*}
\]

We write $N_2$ for this rational curve in $M$.

There are four values of $\lambda$ such that all $a_j$ are equal up to sign; this leads to $a_j = \pm \alpha$ with $\alpha = \frac{3}{8}(5 \pm \sqrt{-7})$ and

$$(u_1, u_2, u_3, d, v, w) = (3\alpha^2, 3\alpha^4, \alpha^6, 0, 4, 2\alpha^3).$$

In this case, $E$ has complex multiplication by the order of discriminant $-7$, and the isogeny $E \to E_1$ is multiplication by $(1 \pm \sqrt{-7})/2$. So in this special situation, we can have three curves of this type.

**Definition 6.3.** We call the curves of geometric genus 1 on $S$ arising as in Scenario (1) **curves of type II**.

See the right part of Figure 5 for how a curve of type II sits inside $S$.

For scenario (2), we consider $E$ with two points $Q, Q'$ of order 4 that span $E[4]$. We set $T = 2Q$, $T' = 2Q'$ and write $D = (O) + (T) + (T') + (T + T')$ for the divisor that is the sum of the 2-torsion points on $E$. Then essentially the only way
Figure 6. **Left:** A curve of type II. It is the preimage in $S$ of the black conic. The dashed line leads to a curve of type I. **Right:** When two of the curves have $a_j = 0$, then we can obtain two curves of type II (given by the solid and the dashed black conics) and two curves of type I (given by the two dotted lines).

See the right part of Figure 4.

We are now going to show that this scenario is impossible. For this, note that the map negating the $y$-coordinate is given on $E_1$, $E_2$ and $E_3$ by $P \mapsto \psi_1(T') - P$, $P \mapsto \psi_2(T) - P$ and $P \mapsto -P$, respectively. Consider $P = Q + Q' \in E$. We have

$$P = (\psi_1(Q + Q'), \psi_2(Q + Q'), \psi_3(Q + Q'))$$

$$= (\psi_1(-Q + Q'), \psi_2(Q - Q'), \psi_3(-Q - Q'))$$

$$= (\psi_1(T') - \psi_1(P), \psi_2(T) - \psi_2(P), -\psi_3(P))$$

$$= \gamma(P),$$

so that $\gamma$ would have $P$ as a fixed point on $X$, which contradicts our assumptions. So this scenario is indeed impossible.

We summarize our findings.

**Theorem 6.4.** Let $S$ be a primary Burniat surface. Then $S$ does not contain rational curves. Depending on the location of the moduli point of $S$ in $M$, $S$ contains the numbers of curves of geometric genus 1 at infinity, of type I and of
Table 1. Curves of geometric genus 1 on $S$, see Theorem 6.4. We use the notations $M_j$, $N_j$ as introduced in Sections 4 and 6. Each line applies to surfaces whose moduli point is in the subset of $M$ given in the ‘∈’ column, but not in any of the subsets given in the ‘∉’ column.

$M_2 \cap N_2$ is the single point $(u_1, u_2, u_3, d, v, w) = (36, 0, 0, 0, 4, 0)$ represented by $(a_1, a_2, a_3, c) = (0, 0, 6, 1)$, whereas $M_4 \cap N_2$ consists of the two points $(3\alpha^2, 3\alpha^4, \alpha^6, 0, 4, 2\alpha^3)$, where $4\alpha^2 - 15\alpha + 18 = 0$, represented by $(-\alpha, -\alpha, -\alpha, i)$.

**7. Rational points on primary Burniat surfaces**

In this section we will assume that everything is defined over $\mathbb{Q}$. Concretely, this means that the curves $E_j$ are curves of genus 1 over $\mathbb{Q}$, the torsion points $T_j$ are rational points on the Jacobian elliptic curves of the $E_j$, the functions $x_j$ are defined over $\mathbb{Q}$, and $c \in \mathbb{Q}$. Then $X$ and $S$ are also defined over $\mathbb{Q}$, and it makes sense to study its set $S(\mathbb{Q})$ of rational points.

**Definition 6.5.** For our purposes, we will say that a primary Burniat surface $S$ is *generic*, if $S$ does not contain curves of type I or II.

By Theorem 6.4, $S$ is generic if and only if no two of the $E_j$ are isomorphic as double covers of $\mathbb{P}^1$, which means that $d \neq 0$. 

The column labeled ‘dim.’ gives the dimension of the corresponding subset of the moduli space.

In particular, the number of curves of geometric genus 1 on a primary Burniat surface can be 6, 7, 8, 9, 10 or 12.

In each case, $\text{Aut}(S)$ acts transitively on the curves of type I and on the curves of type II.

**RATIONAL POINTS ON PRIMARY BURNIAT SURFACES**

In this section we will assume that everything is defined over $\mathbb{Q}$. Concretely, this means that the curves $E_j$ are curves of genus 1 over $\mathbb{Q}$, the torsion points $T_j$ are rational points on the Jacobian elliptic curves of the $E_j$, the functions $x_j$ are defined over $\mathbb{Q}$, and $c \in \mathbb{Q}$. Then $X$ and $S$ are also defined over $\mathbb{Q}$, and it makes sense to study its set $S(\mathbb{Q})$ of rational points.
We recall that $S$ contains six genus 1 curves at infinity; we will soon see that these curves always have rational points, so they are elliptic curves over $\mathbb{Q}$. If some of these curves have positive Mordell-Weil rank, then $S(\mathbb{Q})$ is infinite. The same is true when $S$ contains curves of type I or II that are defined over $\mathbb{Q}$, have a rational point and positive Mordell-Weil rank.

**Definition 7.1.** Let $S$ be a primary Burniat surface. We denote by $S'$ the complement in $S$ of the union of the curves of geometric genus 1 on $S$. Note that $S'(\mathbb{Q})$ is the set of sporadic rational points on $S$.

**Theorem 7.2.** If $S$ a primary Burniat surface, then the set $S'(\mathbb{Q})$ of sporadic rational points on $S$ is finite.

**Proof.** This is a special case of Theorem 2.8. We use the fact that the only low-genus curves on $S$ are the curves of geometric genus 1 that we have excluded from $S'$. \qed

In the remainder of this paper, we will be concerned with computing the set of sporadic rational points explicitly.

We now discuss how to modify the description given in Section 4 when we want to work over $\mathbb{Q}$ instead of over $\mathbb{C}$. We will restrict to the case that the three genus 1 curves $E_1$, $E_2$, $E_3$ whose product contains $X$ are individually defined over $\mathbb{Q}$. Then the two commuting involutions on $E_j$ used in the construction, one without fixed points...
points and one with four fixed points, are also defined over $\mathbb{Q}$. Dividing by the latter, we see that $E_j$ is (as before) a double cover of $\mathbb{P}^1$ ramified in four points, so it can be given by an equation of the form $y^2 = f(x)$ with a polynomial $f$ of degree (at most) 4. The function that is invariant under the second involution and changes sign under the first must then be a function on $\mathbb{P}^1$; we can choose $x$ to be that function. Then the first involution is $(x, y) \mapsto (-x, -y)$ (without the sign change on $y$, it would have fixed points), and the polynomial $f$ must be even. So the curve $E_j$ has (affine) equation

$$E_j: y_j^2 = r_jx_j^4 + s_jx_j^2 + t_j$$

with $r_j, s_j, t_j \in \mathbb{Q}$ and $(s_j^2 - 4r_jt_j)r_jt_j \neq 0$. Note that the parameter $a_j$ in equations (4.1) is then given by $a_j^2 = s_j^2/r_jt_j$. The surface $X$ is given by $x_1x_2x_3 = c$ inside $E_1 \times E_2 \times E_3$. The moduli point on $M$ is given by

$$u_1 = \frac{s_1^2}{r_1t_1} + \frac{s_2^2}{r_2t_2} + \frac{s_3^2}{r_3t_3}, \quad u_2 = \frac{s_1^2s_2^2}{r_1r_2t_1t_2} + \frac{s_2^2s_3^2}{r_2r_3t_2t_3} + \frac{s_3^2s_1^2}{r_3r_1t_1t_3}, \quad u_3 = \frac{s_1^2s_2^2s_3^2}{r_1r_2r_3t_1t_2t_3},$$

$$d = \left( \frac{s_1^2}{r_1t_1} - \frac{s_2^2}{r_2t_2} \right) \left( \frac{s_2^2}{r_2t_2} - \frac{s_3^2}{r_3t_3} \right) \left( \frac{s_3^2}{r_3t_3} - \frac{s_1^2}{r_1t_1} \right), \quad v = \frac{r_1r_2r_3}{t_1t_2t_3}c^4 + \frac{t_1t_2t_3}{r_1r_2r_3}c^{-4}$$

and

$$w = s_1s_2s_3\left( \frac{c^2}{t_1t_2t_3} + \frac{c^{-2}}{r_1r_2r_3} \right).$$

The generators of $\Gamma$ act as follows.

$$\gamma_1: (x_1, y_1, x_2, y_2, x_3, y_3) \mapsto (x_1, y_1, -x_2, -y_2, -x_3, y_3)$$
$$\gamma_2: (x_1, y_1, x_2, y_2, x_3, y_3) \mapsto (-x_1, y_1, x_2, y_2, -x_3, -y_3)$$
$$\gamma_3: (x_1, y_1, x_2, y_2, x_3, y_3) \mapsto (-x_1, -y_1, -x_2, y_2, x_3, y_3).$$

**Remark 7.3.** One also obtains a primary Burniat surface defined over $\mathbb{Q}$, when the three curves $E_j$ are defined over a cyclic cubic extension $K$ of $\mathbb{Q}$ and form a Galois orbit (and $c \in \mathbb{Q}$). Then $\Gamma$ is a $\mathbb{Q}$-group scheme that splits over $K$. We do not look into this case further, or consider the question for which moduli points $p \in M(\mathbb{Q})$ a corresponding primary Burniat surface can be defined over $\mathbb{Q}$.

The twists coming up in the proof of Remark 2.9 are in our case parameterized by the Galois cohomology group

$$H^1(\mathbb{Q}, \Gamma) \cong H^1(\mathbb{Q}, \mu_2)^3 \cong (\mathbb{Q}^*/(\mathbb{Q}^*)^2)^3;$$
its elements can be represented by triples \((d_1, d_2, d_3)\) of squarefree integers. The corresponding twist \(X_{\xi}\) is then given by

\[
X_{(d_1, d_2, d_3)}: \begin{cases} 
  d_3 y_1^2 = r_1 d_2^2 d_3 x_1^4 + s_1 d_2 d_3 x_1^2 + t_1 \\
  d_1 y_2^2 = r_2 d_1^2 d_3 x_2^4 + s_2 d_1 d_3 x_2^2 + t_2 \\
  d_2 y_3^2 = r_3 d_1^2 d_2 x_3^4 + s_3 d_1 d_2 x_3^2 + t_3 \\
  d_1 d_2 d_3 x_1 x_2 x_3 = c.
\end{cases}
\]

We can restrict the prime divisors of the \(d_j\) to the set consisting of the prime 2 and the primes \(p\) of bad reduction, i.e., such that the reduction of \(X\) contains a fixed point of \(\gamma = \gamma_1 \gamma_2 \gamma_3\). To make this explicit, we have to define a kind of ‘discriminant’ for \(X\) that vanishes if and only if \(X\) passes through one of the fixed points. This will be the case if and only if \(c = x_1(P_1)x_2(P_2)x_3(P_3)\) for some \(P_j \in E_j\) that are fixed points of \((x_j, y_j) \mapsto (x_j, -y_j)\), i.e., for points \(P_j = (\alpha_j, 0)\) with \(r_j \alpha_j^2 + s_j \alpha_j^2 + t_j = 0\). Equivalently, \(c^2 = \beta_1 \beta_2 \beta_3\) with \(\beta_j\) a root of \(r_j X^2 + s_j X + t_j\).

We therefore look at

\[
\prod_{\varepsilon_1, \varepsilon_2, \varepsilon_3 = \pm 1} \left( 8 r_1 r_2 r_3 c^2 - (s_1 + \varepsilon_1 \Delta_1)(s_2 + \varepsilon_2 \Delta_2)(s_3 + \varepsilon_3 \Delta_3) \right),
\]

where \(\Delta_j = \sqrt{s_j^2 - 4 r_j t_j}\). We can divide this by \(2^{24} r_1^4 r_2^4 r_3^4\) and obtain

\[
D = r_1^4 r_2^4 r_3^4 c^{16} + r_1^3 r_2^3 r_3^3 s_1 s_2 s_3 c^{14} + r_1^2 r_2^2 r_3^2 (4 \sigma_1 - 2 \sigma_2 + \sigma_3) c^{12} \\
+ r_1 r_2 r_3 s_1 s_2 s_3 (-5 \sigma_1 + \sigma_2) c^{10} + (6 \sigma_1^2 - 4 \sigma_1 \sigma_2 - 2 \sigma_1 \sigma_3 + \sigma_1 \sigma_4 + \sigma_2^2) c^8 \\
+ s_1 s_2 s_3 t_1 t_2 t_3 (-5 \sigma_1 + \sigma_2) c^6 + t_1^2 t_2^3 t_3^2 (4 \sigma_1 - 2 \sigma_2 + \sigma_3) c^4 \\
+ s_1 s_2 s_3 t_1^2 t_2^3 t_3^2 c^2 + t_1^4 t_2^4.
\]

Here we have set

\[
\sigma_1 = r_1 r_2 r_3 t_1 t_2 t_3 \\
\sigma_2 = r_1 r_2 s_3^2 t_1 t_2 + r_1 r_3 s_2^2 t_1 t_3 + r_2 r_3 s_1^2 t_2 t_3 \\
\sigma_3 = r_1 s_2 s_3^2 t_1 + r_2 s_1 s_3^2 t_2 + r_3 s_1^2 s_2^2 t_3 \\
\sigma_4 = s_1^2 s_2^2 s_3^2.
\]

We see that \(X\) does not pass through fixed points of \(\gamma\) and is smooth (and therefore \(S\) is smooth) if and only if \(c D \neq 0\) and the curves \(E_j\) are smooth. The latter condition is

\[
0 \neq \prod_{j=1}^3 (r_j t_j (s_j^2 - 4 r_j t_j)) = \sigma_1 (\sigma_4 - 4 \sigma_3 + 16 \sigma_2 - 64 \sigma_1).
\]

We obtain the following result.
Lemma 7.4. Assume that the \( r_j, s_j, t_j \) and \( c \) are integers satisfying
\[
rt_j(s_j^2 - 4r_jt_j) \neq 0 \quad \text{for all} \quad j \quad \text{and} \quad c \neq 0, \quad D \neq 0.
\]
Let \( d_1, d_2, d_3 \) be squarefree integers. Then the twist \( X_{(d_1,d_2,d_3)} \) of \( X \to S \) fails to have points over some completion of \( \mathbb{Q} \) unless all the prime divisors of \( d_1d_2d_3 \) are prime divisors of \( 2cD\sigma_1(\sigma_4 - 4\sigma_3 + 16\sigma_2 - 64\sigma_1) \).

We now consider the genus 1 curves at infinity on \( X \) and on \( S \). On \( X \), a typical \( \Gamma \)-orbit of these is as follows. We fix a point at infinity on \( E_1 \) and a point with zero \( x \)-coordinate on \( E_2 \), say those with \( y_1/x_1^2 = \sqrt{r_1} \) and \( y_2 = \sqrt{r_2}; \) call them \( P \) and \( Q \) and the other points with the same \( x \)-coordinate \( \bar{P} \) and \( \bar{Q} \). Then the curve \( \{P\} \times \{Q\} \times E_3 \) is contained in \( X \), and the generators of \( \Gamma \) act as follows.

\[
\begin{align*}
\gamma_1: (P, Q, R) & \mapsto (P, \bar{Q}, -R + T_3) \\
\gamma_2: (P, Q, R) & \mapsto (P, Q, R + T_3) \\
\gamma_3: (P, Q, R) & \mapsto (P, Q, R).
\end{align*}
\]

The orbit of the curve consists of four curves, the other three being \( \{\bar{P}\} \times \{Q\} \times E_3 \), \( \{P\} \times \{Q\} \times E_3 \) and \( \{P\} \times \{Q\} \times E_3 \). The action splits into independent actions on \( \{P, P\} \) and on \( \{Q, Q\} \times E_3 \). Invariants for the latter are given by \( x_3^2 \) and \( \sqrt{t_2x_3y_3} \) (where \( Q \mapsto \bar{Q} \) corresponds to \( \sqrt{t_2} \mapsto -\sqrt{t_2} \)). There is the relation
\[
(\sqrt{t_2x_3y_3})^2 = t_2x_3^2(r_3x_3^4 + s_3x_3^2 + t_3),
\]
which in terms of \( Y = \sqrt{t_2x_3y_3} \) and \( X = x_3^2 \) can be written as
\[
Y^2 = t_2X(r_3X^2 + s_3X + t_3),
\]
which is the quadratic twist by \( t_2 \) of the Jacobian elliptic curve of \( E_3 \). Switching the roles of zero and infinity, we obtain the \( t_2 \)-twist of the same elliptic curve. The other curves we obtain by cyclic permutation of the indices. This gives us the quadratic twists by \( t_3 \) and by \( r_3 \) of the Jacobian elliptic curve of \( E_1 \) and the quadratic twists by \( t_1 \) and by \( r_1 \) of the Jacobian elliptic curve of \( E_2 \). These six curves are arranged in the form of a hexagon, with intersection points at the origin and the obvious (rational) point of order 2. We can now conclude:

Theorem 7.5. We always have \( \#S(\mathbb{Q}) \geq 6 \). \( S'(\mathbb{Q}) \) is finite, and \( S(\mathbb{Q}) \) is infinite if and only if at least one of the genus 1 curves on \( S \) has a rational point and positive rank.

Proof. The first statement follows, since the six points of intersection of two of the elliptic curves in \( S \) are always rational. For the second statement, we recall that \( S'(\mathbb{Q}) \) is finite by Theorem 7.2. Therefore \( S(\mathbb{Q}) \) is infinite if and only if one of the genus 1 curves on \( S \) has infinitely many points, i.e., it has a rational point and positive rank.
8. Determining the set of rational points on the twists

This section is dedicated to the discussion how to determine the set $X_\xi(\mathbb{Q})$ of rational points on the relevant twists of $X$. For this, note first that $X_\xi$ is of the same form as $X$, as shown by the defining equations (7.1). For the description of the available methods, it is therefore sufficient to deal with $X$ itself.

We have the three projections $\psi_j : X \leftrightarrow E_1 \times E_2 \times E_3 \to E_j$ at our disposal. There are two cases.

8.1. **Some $E_j$ fails to have rational points.** If we can show that $E_j(\mathbb{Q}) = \emptyset$ for some $j$, then clearly $X(\mathbb{Q}) = \emptyset$, too. To decide whether $E_j$ has rational points, we can, on the one hand, try to find a rational point by a systematic search, and, on the other hand, try to prove that no rational point exists by performing a ‘second descent’ on the 2-covering $E_j$ of $J_j$, its Jacobian elliptic curve. The latter can be done explicitly by computing the ‘2-Selmer set’ of $E_j$, compare [BS09]; if this set is empty, then $E_j(\mathbb{Q}) = \emptyset$ as well. If necessary, a further descent step can be performed on the two-coverings of $E_j$, compare [Sta05].

8.2. **All $E_j$ have rational points.** If we find some $P_j \in E_j(\mathbb{Q})$ for all $j$, then the $E_j$ are elliptic curves, and we can try to determine the free abelian rank of the groups $E_j(\mathbb{Q})$. The standard tool for this is Cremona’s mwrank program as described in [Cre97], whose functionality is included in Magma and SAGE. This is based on 2-descent. If this is not sufficient to determine the rank, then one can also perform ‘higher descents’, see for example [CFO+08] and the references given there.

There are several cases, according to how many of the sets $E_j(\mathbb{Q})$ are finite.

**All $E_j(\mathbb{Q})$ are finite.** Then $(E_1 \times E_2 \times E_3)(\mathbb{Q})$ is finite, and we only have to check which of these finitely many points lie on $X$.

**Two of the $E_j(\mathbb{Q})$ are finite.** Say $E_1(\mathbb{Q})$ and $E_2(\mathbb{Q})$ are finite. Then we can easily determine the set of rational points on $X$ by checking the finitely many fibers of $(\psi_1, \psi_2) : X \to E_1 \times E_2$ above rational points of $E_1 \times E_2$; note that these fibers are finite (of size two), hence it is easy to determine their rational points.

**Exactly one of the $E_j(\mathbb{Q})$ is finite.** Say $E_1(\mathbb{Q})$ is finite. In this case, we can at least reduce to the finitely many fibers of $\psi_1$ over rational points on $E_1$. These fibers are (generically) smooth curves of genus 5 contained in the product of the two other genus 1 curves (and defined by the relation that the product of the two $x$-coordinates is constant).
We then need a way of determining the set of rational points on a genus 5 curve $C$ sitting in a product of two elliptic curves of positive rank. After making a transformation $x \leftarrow c'/x$ of the $x$-coordinate on one of the two genus 1 curves, the product condition becomes the condition that the two $x$-coordinates are equal. The curve $C$ can then be written as a bidouble cover of $\mathbb{P}^1$, given by a pair of equations

$$u^2 = a_0x^4 + a_1x^2z^2 + a_2z^4, \quad v^2 = b_0x^4 + b_1x^2z^2 + b_2z^4.$$ 

This curve is a double cover of the hyperelliptic curve

$$D: y^2 = (a_0x^4 + a_1x^2z^2 + a_2z^4)(b_0x^4 + b_1x^2z^2 + b_2z^4),$$

which is of genus 3 (unless the two factors have common roots), so the Jacobian of $C$ splits up to isogeny into a product of three elliptic curves (with the Jacobians of $E_1$ and $E_2$ among them) and an abelian surface. More precisely, $D$ covers the genus 1 curve

$$E: y^2 = (a_0x'^2 + a_1x'z' + a_2z'^2)(b_0x'^2 + b_1x'z' + b_2z'^2)$$

and the genus 2 curve

$$F: w^2 = x'z'(a_0x'^2 + a_1x'z' + a_2z'^2)(b_0x'^2 + b_1x'z' + b_2z'^2)$$

(where $(x' : z' : w) = (x^2 : z^2 : xyz)$). If the third elliptic curve has rank zero or the Jacobian of $F$ has Mordell-Weil rank at most 1 (the rank can usually be determined by the methods of [Sto01]), then methods are available that in many cases will be able to determine $C(\mathbb{Q})$, see for example [BS10]. Even when the rank is 2 or larger, ‘Elliptic curve Chabauty’ methods might apply to $F$ or also $D$, see [Bru03].

The possible degenerations of a fiber of the genus 5 fibration $X \to E_j$ are as follows.

1. A curve of geometric genus 3 with two nodes. Then $D$ and $F$ above each degenerate to a curve of (geometric) genus 1, and we can hope that at least one of them has only finitely many rational points.

2. Two curves of geometric genus 1 intersecting in four points. These map to curves of type I on $S$; we can try to find out whether they have finitely many or infinitely many rational points.

All $E_j(\mathbb{Q})$ are infinite. In this situation, there must be finitely many points $p_1, \ldots, p_r \in E_j(\mathbb{Q})$, such that the sporadic rational points of $X$ are contained in the fibers over $p_1, \ldots, p_r$. But there are no methods available so far to determine these points, hence we cannot yet deal with this situation.

We end this section by taking a quick look at the situation when there are curves of type I or II on $S$ and observe the following.
Remark 8.1. If a curve of type I or II on $S$ has only finitely many rational points, it will not present any difficulties. Otherwise:

(I) When there is a curve $E$ of type I (defined over $\mathbb{Q}$) on $S$ such that $E(\mathbb{Q})$ is infinite, then there will be some twist $X_\xi$ of $X$ such that $E$ lifts to an elliptic curve $E'$ on $X_\xi$ with infinitely many rational points. Since $E'$ is isomorphic to a product of two of the $E_j,\xi$, we need the third $E_j,\xi$ to be of rank 0 for our approach to work.

(II) When there is a curve $E$ of type II (defined over $\mathbb{Q}$) on $S$ such that $E(\mathbb{Q})$ is infinite, then there will again be some twist $X_\xi$ of $X$ such that $E$ lifts to an elliptic curve $E'$ on $X_\xi$ with infinitely many rational points. In this case, $E'$ is isogenous to all three $E_j,\xi$, so all three curves will have positive rank, and our methods will necessarily fail.

9. Examples

We first give a number of examples in the generic case, when $S$ does not have curves of types I or II.

As a first example, take

$$E_1: y_1^2 = -x_1^4 - 1, \quad E_2: y_2^2 = x_2^4 - 1, \quad E_3: y_3^2 = x_3^4 + 1$$

and $c = 2$. All three curves have bad reduction only at $2$, and $D = 50625 = 3^4 \cdot 5^4$, so the set of bad primes is $\{2, 3, 5\}$. There are $2^{3 \cdot 4} = 4096$ triples $(d_1, d_2, d_3)$ to be checked. Of these, only $(1, -1, 1), (1, -1, -1), (2, -2, 2)$ and $(2, -2, -2)$ satisfy the condition that the twisted product of the $E_j$ has a rational point. It turns out that all the twisted genus 1 curves that occur have only finitely many points. We can find them all and therefore determine the sets $X_{(d_1, d_2, d_3)}(\mathbb{Q})$. It turns out that these sets are empty for the triples $(2, -2, 2)$ and $(2, -2, -2)$, and for the other two triples all these points map to points at infinity on $S$; they fall into five orbits each under the action of $\Gamma$ on the two twists. This results in the following.

Proposition 9.1. Let $X \subset E_1 \times E_2 \times E_3$ with $E_j$ as in (9.1) be defined by $x_1 x_2 x_3 = 2$ and set $S = X/\Gamma$. Then $S'(\mathbb{Q}) = \emptyset$ and $\#S(\mathbb{Q}) = 10$.

As our second example, we consider

$$E_1: y_1^2 = -x_1^4 - 1, \quad E_2: y_2^2 = x_2^4 + 2x_2^2 + 2, \quad E_3: y_3^2 = -2x_3^4 - 2x_3^2 + 1$$

and $c = 1$. The curves have bad reduction at most at $2$ and $3$, and $D = 256 = 2^8$, so the set of bad primes is $\{2, 3\}$. There are six triples $(d_1, d_2, d_3)$ such that the corresponding twist of $E_1 \times E_2 \times E_3$ has rational points, namely $(1, -1, 1), (1, -1, 2), (1, -2, 2), (-2, -1, 1), (-2, -1, 2)$ and $(-2, -2, 2)$. For the third and the last, the twisted product has only finitely many rational points. The third gives no contribution (the rational points are not on the twist of $X$), whereas
the last gives two rational points at infinity on $S$. For the remaining four triples, exactly one of the twisted curves has infinitely many rational points (rank 1). However, the other two curves have only rational points with $x_j \in \{0, \infty\}$, so all rational points on the corresponding twists of $X$ map to points at infinity of $S$, of which there are now infinitely many (two of the six genus 1 curves at infinity on $S$ have infinitely many rational points). We obtain the following.

**Proposition 9.2.** Let $X \subset E_1 \times E_2 \times E_3$ with $E_j$ as in (9.2) be defined by $x_1 x_2 x_3 = 1$ and set $S = X/\Gamma$. Then $S'(\mathbb{Q}) = \emptyset$ and $S(\mathbb{Q})$ is infinite.

As our third example, we take

\begin{align}
E_1: y_1^2 &= 2x_1^4 + x_1^2 + 1, \\
E_2: y_2^2 &= x_2^4 - x_2^2 + 1, \\
E_3: y_3^2 &= x_3^4 - x_3^2 + 4
\end{align}

and $c = 1$. The curves have bad reduction at 2, 3, 5 and 7, and $D = 436 = 2^2 \cdot 109$, so that the set of bad primes is $\{2, 3, 5, 7, 109\}$. There are two triples $(d_1, d_2, d_3)$ such that the corresponding twist of the product has rational points; they are $(1, 1, 1)$ and $(1, 1, 2)$. In both cases, two of the twisted curves have rank 1 and the third has finitely many rational points. For the second triple, these points all have $x \in \{0, \infty\}$, so that we do not obtain a contribution to $S'(\mathbb{Q})$. For the first triple, the twist of $E_2$ has eight rational points, four of which have $x \in \{0, \infty\}$ and the other four have $x \in \{\pm 1\}$. For each of these four points, the curve $D$ is given by

$$D: y^2 = (2x^4 + x^2 + 1)(4x^4 - x^2 + 1).$$

The elliptic curve $E$ covered by it has rank 1, but for the genus 2 curve

$$F: y^2 = x(2x^2 + x + 1)(4x^2 - x + 1)$$

that is also covered by $D$, one can show (using the algorithm of [Sto01]) that its Jacobian has Mordell-Weil rank 1. Then Chabauty’s method combined with the Mordell-Weil sieve (see [BS10]) can be used to show that

$$F(\mathbb{Q}) = \{\infty, (0, 0), (1, 4), (1, -4)\}.$$

Note that the twist $(1, 1, 1)$ is the original surface $X$. Translating back to the coordinates on $E_1$, $E_2$, $E_3$, we see that all points on $X$ must have $x_1, x_2, x_3 \in \{\pm 1\}$. Since each of the three curves has a pair of rational points with $x = 1$ and also with $x = -1$, this gives a total of 32 rational points on $X$ mapping to $S'$. They fall into four $\Gamma$-orbits and therefore give rise to four rational points on $S'$. Since of the six elliptic curves at infinity on $S$, four have positive rank, we obtain the following.

**Proposition 9.3.** Let $X \subset E_1 \times E_2 \times E_3$ with $E_j$ as in (9.3) be defined by $x_1 x_2 x_3 = 1$ and set $S = X/\Gamma$. Then $S'(\mathbb{Q})$ consists of four points and $S(\mathbb{Q})$ is infinite.
To conclude, we present an example where $S$ contains a curve of type I with infinitely many rational points. We take

\begin{align*}
E_1 : y_1^2 = 2x_1^4 + x_1^2 + 1, & \quad E_2 : y_2^2 = x_1^4 + x_2^2 + 2, & \quad E_3 : y_3^2 = x_3^4 - x_3^2 + 1
\end{align*}

and $c = 1$. The curves have bad reduction at 2, 3 and 7, and $D = 100 = 2^2 \cdot 5^2$, so that the set of bad primes is $\{2, 3, 5, 7\}$. There are four triples $(d_1, d_2, d_3)$ such that the corresponding twist of the product has rational points; they are $(1, 1, 1)$, $(1, 1, 2)$, $(2, 1, 1)$ and $(2, 1, 2)$. For the twists corresponding to the last three, there is always one twisted $E_j$ that has only finitely many rational points, all of which have $x \in \{0, \infty\}$, so we obtain no contribution outside the curves at infinity on $S$ from these twists. For the first twist (which is $X$ itself), we have that $E_1$ and $E_2$ both have rank 1 and $E_3$ has eight rational points, four of which have $x \notin \{0, \infty\}$. The fibers above these four points form a $\Gamma$-orbit, and each fiber splits as a union of two elliptic curves intersecting in four points, thus producing a type I curve on $S$. The curves on $X$ are isomorphic to $E_1$ (and $E_2$); they therefore have infinitely many rational points, and the same is true for the type I curve on $S$ they map to. Since there are no further contributions, we have the following result.

**Proposition 9.4.** Let $X \subset E_1 \times E_2 \times E_3$ with $E_j$ as in (9.4) be defined by $x_1x_2x_3 = 1$ and set $S = X/\Gamma$. Then $S$ contains exactly one curve of type I, which has infinitely many rational points, and no curve of type II. Furthermore, three out of the six curves at infinity on $S$ contain infinitely many rational points. There are no sporadic rational points on $S$.

*Proof.* It remains to show that the type I curve detected above is the only extra low-genus curve on $S$. This follows from the discussion in Section 6, since the moduli point of $S$ is given by $(u_1, u_2, u_3, d, v, w) = (2, \frac{5}{1}, \frac{1}{3}, 0, 4, -1)$, which is in $N_1$, but neither in $M_2$, $M_4$ nor in $N_2$. Also, one checks that three of the six curves at infinity have positive rank. \qed
