## ABSTRACT

Reverse gyrase is a topoisomerase that introduces positive supercoils into DNA in an ATP-dependent manner. It is unique to hyperthermophilic archaea and eubacteria, and has been proposed to protect their DNA from damage at high temperatures. Cooperation between its N-terminal helicase-like and the C-terminal topoisomerase domain is required for positive supercoiling, but the precise role of the helicase-like domain is currently unknown. Here, the characterization of the isolated helicase-like domain from *Thermotoga maritima* reverse gyrase is presented. We show that the helicase-like domain contains all determinants for nucleotide binding and ATP hydrolysis. Its intrinsic ATP hydrolysis is significantly stimulated by ssDNA, dsDNA and plasmid DNA. During the nucleotide cycle, the helicase-like domain switches between high- and low-affinity states for dsDNA, while its affinity for ssDNA in the ATP and ADP states is similar. In the context of reverse gyrase, the differences in DNA affinities of the nucleotide states are smaller, and the DNA-stimulated ATPase activity is strongly reduced. This inhibitory effect of the topoisomerase domain decelerates the progression of reverse gyrase through the nucleotide cycle, possibly providing optimal coordination of ATP hydrolysis with the complex reaction of DNA supercoiling.

## INTRODUCTION

Reverse gyrase is the only topoisomerase that introduces positive supercoils into DNA at the expense of ATP hydrolysis (1). It is unique to hyperthermophilic archaea and eubacteria. Deletion of the reverse gyrase gene in a

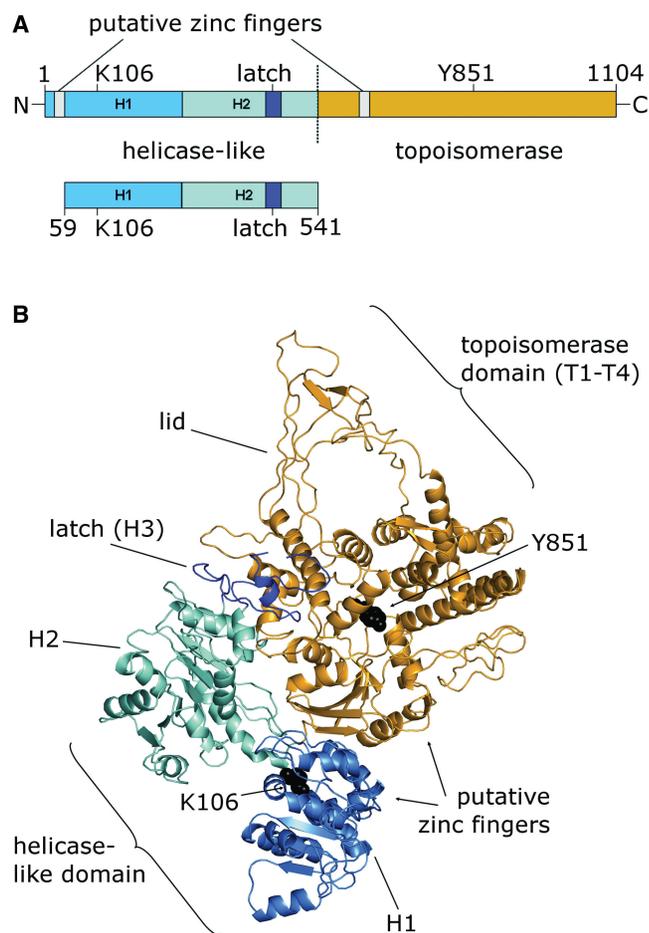

hyperthermophilic archaeon leads to growth retardation at higher temperatures, but the organism is still able to survive at 90°C, demonstrating that reverse gyrase is not strictly required for hyperthermophilic life (2,3). The *in vivo* function of reverse gyrase is not clear. A heat-protective DNA chaperone activity (4) and a DNA renaturase activity (5) have been reported, indicating that reverse gyrase protects DNA from damage at high temperatures.

Reverse gyrase consists of an N-terminal helicase-like domain, fused to a C-terminal topoisomerase I domain. While most reverse gyrases are monomeric, a covalent connection between the two domains is not required for positive supercoiling activity. The *Methanopyrus kandleri* reverse gyrase is a dimeric enzyme, with the helicase-like and part of the topoisomerase domain in one subunit, and the remainder of the topoisomerase domain provided by the second subunit (6,7). Furthermore, an active reverse gyrase can be reconstituted by mixing separately produced helicase-like and topoisomerase domains (8; Hilbert, M. and Klostermeier, D., unpublished data). Nevertheless, a functional cooperation of helicase-like and topoisomerase domains is required for positive supercoiling by reverse gyrase (8,9).

The helicase-like domain shares the three-dimensional structure with helicases of the superfamily (SF) 2, namely two tandem RecA-folds (H1, H2) connected by a linker (Figure 1). In reverse gyrase, the subdomain H2 is interrupted by the so-called latch domain (H3) that shows homology to the region of the transcription termination factor Rho that is involved in RNA binding (10). The reverse gyrase helicase-like domain comprises all signature motifs of SF2 helicases, but the sequences of these motifs show large deviations from the consensus (Supplementary Figure S1). These sequence variations may be responsible for the lack of unwinding activity by reverse gyrase or the isolated helicase-like domain (8). Reverse gyrase does not catalyze relaxation in the absence of nucleotides, whereas the topoisomerase domain on its own can relax DNA in

**Figure 1.** Reverse gyrase and its helicase-like domain. (A) Full-length reverse gyrase, consists of an N-terminal helicase-like domain [H1, light blue, H2, cyan, H3 (latch), blue] and a C-terminal topoisomerase domain (orange). The helicase-like domain construct comprises the helicase-like domain (H1 and H2), and the latch-domain H3 that is inserted into H2. The positions of K106 in the Walker A motif and of the catalytic tyrosine, Y851 (black), and the putative zinc fingers (gray) are indicated. (B) Structure of *A. fulgidus* reverse gyrase [PDB-ID 1GKU, Ref. (10)], color-coded as in (A). The regions carrying the putative zinc fingers are missing in the electron density.

the absence of nucleotides, but lacks supercoiling activity (8,11). It has been suggested that the latch domain suppresses relaxation in reverse gyrase in the absence of nucleotides (12).

Based on the crystal structure of the reverse gyrase from *Archaeoglobus fulgidus* (10), a mechanism for positive supercoiling has been postulated that is based on a conformational change of the helicase-like domain as the initiating step, leading to a closure of the cleft between the two RecA-like subdomains. This conformational change may then allow for release of the latch domain, and for swinging-up of the 'lid' region in the topoisomerase domain, which is required for strand passage (Figure 1B). We have recently shown that such a conformational change occurs in SF2 helicases in response to the cooperative binding of ATP and nucleic acid substrates (13). Furthermore, we have demonstrated that reverse gyrase can use ATP or ATP $\gamma$ S as the energy source for positive

supercoiling, suggesting that both nucleotides can power the conformational cycle (14). This ATP $\gamma$ S-dependent activity has also been observed for the translation factor eIF4A, a member of the SF2 helicase family (15), which further indicates mechanistic similarities of the reverse gyrase helicase-like domain and SF2 helicases. Although the helicase-like domain is a crucial element for ATP-dependent positive supercoiling by reverse gyrase, its role is currently not well understood. We present here the characterization of nucleotide binding, ATP hydrolysis, DNA binding and DNA-stimulation of the ATPase activity for the isolated helicase-like domain of *Thermotoma maritima* reverse gyrase and compare it to the properties of reverse gyrase. The helicase-like domain confers nucleotide-dependent DNA binding to reverse gyrase. The isolated domain is an efficient DNA-stimulated ATPase, but the topoisomerase domain in reverse gyrase exerts a moderating effect onto the ATPase activity, slowing down the nucleotide cycle by a factor of 10. This intra-molecular inhibition suggests that the helicase-like domain is harnessed by reverse gyrase to provide efficient coupling of ATPase activity with the supercoiling reaction.

## MATERIALS AND METHODS

### Cloning, mutagenesis, protein production and purification

The region encoding the helicase-like domain of reverse gyrase (E59-R541, rGyr\_hel) was PCR-amplified from the full-length gene and cloned into pET28a using NcoI and XhoI restriction sites. Site-directed mutagenesis was performed according to the Quikchange protocol (Stratagene, La Jolla, CA, USA).

rGyr\_hel was produced at 37°C in *Escherichia coli* Rosetta (DE3) (Invitrogen, Paisley, U.K) in autoinducing medium (16), and cells were harvested after 24 h. All purification steps were performed at room temperature. Cells were disrupted in a Microfluidizer in 50 mM Tris/HCl, pH 7.5, 1 M NaCl, 10 mM MgCl<sub>2</sub>, 10  $\mu$ M Zn(OAc)<sub>2</sub>, 2 mM BME and the crude extract was cleared by centrifugation. The NaCl concentration of the supernatant was adjusted to 0.2 M, and it was applied to a SP sepharose column equilibrated in 50 mM Tris/HCl, pH 7.5, 0.2 M NaCl, 10 mM MgCl<sub>2</sub>, 10  $\mu$ M Zn(OAc)<sub>2</sub>, 2 mM BME. rGyr\_hel was eluted in a linear gradient from 0.2–1 M NaCl, dialyzed against 50 mM Tris/HCl, pH 7.5, 0.2 M NaCl, 10 mM MgCl<sub>2</sub>, 10  $\mu$ M Zn(OAc)<sub>2</sub>, 2 mM BME, and applied to a Q sepharose column equilibrated in the same buffer. rGyr\_hel was collected in the flowthrough. Final purification was achieved via size-exclusion chromatography on a calibrated S200 column in 50 mM Tris/HCl, pH 7.5, 0.2 M NaCl, 10 mM MgCl<sub>2</sub>, 10  $\mu$ M Zn(OAc)<sub>2</sub>, 2 mM BME. rGyr\_hel elutes as a monomer from a calibrated size-exclusion chromatography column (apparent molecular weight: 49.8 kDa, calculated: 56.3 kDa). Protein concentration was determined photometrically using the calculated extinction coefficient at 280 nm of 56 309 M<sup>-1</sup> cm<sup>-1</sup>. From 1 l of bacterial culture, 4 mg of rGyr\_hel with >98% purity (as judged from SDS-PAGE with Coomassie staining) were obtained. The pure protein was concentrated,

shock-frozen in liquid nitrogen, and stored at  $-80^{\circ}\text{C}$ . Full-length reverse gyrase was purified as described (14).

#### Adenine nucleotides and RNA and DNA substrates

Adenine nucleotides were purchased from Pharma Waldhof (Mannheim, Germany) or Jena Bioscience (Jena, Germany), and checked for impurities by reverse-phase HPLC on a C18 column in 0.1 M sodium phosphate, pH 6.5. Oligonucleotides for ssDNA or dsDNA substrates were obtained from Purimex (Grebstein, Germany). The sequence of the 60-base ssDNA was 5'-(fluorescein)-AAGC CAAGCT TCTAGAGTCA GCCCGTGATA TTCATT ACTT CTTATCCTAG GATCCCCGTT-3', and the dsDNA substrate was formed by annealing the complementary strand. These substrates contain a preferred cleavage site (17,18) for reverse gyrase; cleavage occurs between the two underlined nucleotides. PolyU-RNA was purchased from Sigma (Hamburg, Germany).

#### ATPase assays

Steady state ATPase activity was measured in a spectroscopic enzymatic assay that couples ADP production to the oxidation of NADH as described (14). Assay conditions were 50 mM Tris/HCl, pH 7.5, 0.15 M NaCl, 10 mM  $\text{MgCl}_2$ , 100  $\mu\text{M}$   $\text{Zn}(\text{OAc})_2$ , 2 mM BME, 0.4 mM PEP and 0.2 mM NADH, 23  $\mu\text{g ml}^{-1}$  LDH, 37  $\mu\text{g ml}^{-1}$  PK. ATPase activity at  $75^{\circ}\text{C}$  was determined in 50 mM Tris/HCl, pH 7.5, 0.15 M NaCl, 10 mM  $\text{MgCl}_2$ , 100  $\mu\text{M}$   $\text{Zn}(\text{OAc})_2$ , 2 mM BME, 10% (w/v) PEG 8000 by mixing 1  $\mu\text{M}$  enzyme, 2 mM ATP and the respective nucleic acid substrate, taking aliquots at different time points, and analyzing the nucleotide composition by reverse-phase HPLC as described (14).

#### Fluorescence measurements

Dissociation constants of rGyr\_hel/nucleotide complexes were determined in fluorescence equilibrium titrations at  $37^{\circ}\text{C}$  using 1  $\mu\text{M}$  of the fluorescent ADP analog mantADP (19) and in competitive titrations of the mantADP/rGyr\_hel complex with ADP,  $\text{ATP}\gamma\text{S}$ , ADPNP, ADPCP and ATP, and analyzed as described (14).

Dissociation constants of reverse gyrase/DNA complexes were determined using 5'-fluorescein-labeled DNA and the steady-state anisotropy of fluorescein as a probe for binding. The DNA concentrations were 25 nM for titrations with rGyr\_hel, and 10 nM for rGyr\_fl, unless stated otherwise. Dissociation constants were obtained by analysis of the data using the solution of a quadratic equation describing a one-site binding model as described (14), or with the Hill equation.

#### Helicase assay

Helicase activity was tested via the displacement of a 10-mer from a 10/50-mer substrate (2 nM) by 10  $\mu\text{M}$  rGyr\_hel in 20 mM HEPES/NaOH, pH 7.5, 70 mM KCl, 1 mM  $\text{MgOAc}$ , 10% (v/v) glycerol, 2 mM DTT and 1 mg/ml BSA as described for eIF4A (20). The ATP concentration was 2 mM.

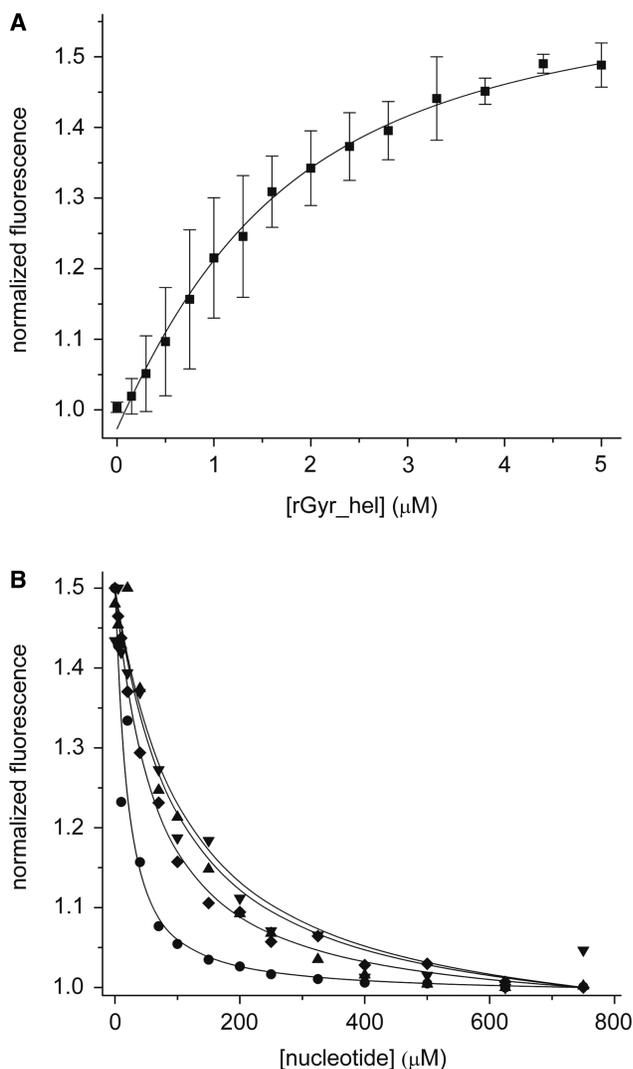

## RESULTS

### Nucleotide binding and ATPase properties of the helicase-like domain

The role of the helicase-like domain for DNA supercoiling by reverse gyrase is currently unknown. A detailed understanding of nucleotide binding and hydrolysis by the helicase-like domain and its interaction with DNA, isolated and in the context of reverse gyrase, is a pre-requisite to delineate its function within reverse gyrase. To this end, we subcloned a DNA fragment coding for amino acids 59–541 of *T. maritima* reverse gyrase (rGyr\_hel). This construct comprises the two RecA-like domains H1 and H2, and the so-called latch domain H3, but lacks the N-terminal putative zinc finger (Figure 1). The nucleotide binding properties of rGyr\_hel were investigated in fluorescent equilibrium titrations using the fluorescent ADP analog mantADP (Figure 2), which we previously used as a probe for nucleotide binding to reverse gyrase (14). Upon binding to rGyr\_hel, the mant fluorescence increases 1.5-fold (Figure 2A). The fluorescence signal returns to the value for free mantADP upon displacement with ADP, confirming that mantADP binds to the ADP binding site and is thus suitable to study nucleotide binding to rGyr\_hel. The  $K_d$  value of the mantADP/rGyr\_hel complex determined from the titration curves is  $1.1 \pm 0.1 \mu\text{M}$ . In the displacement titration with ADP (Figure 2B), a  $K_d$  value of  $2.6 \pm 0.8 \mu\text{M}$  was determined for the ADP complex. The  $K_d$  value of the rGyr\_hel/AMP complex is three orders of magnitude higher ( $1600 \pm 231 \mu\text{M}$ ), demonstrating that interactions with the  $\beta$ -phosphate provide high affinity binding of adenine nucleotides to rGyr\_hel. The ATP analogs  $\text{ATP}\gamma\text{S}$ , ADPNP and ADPCP are bound less tightly than ADP (Figure 2B), with  $K_d$  values for the complexes of  $10.9 \pm 0.8 \mu\text{M}$  ( $\text{ATP}\gamma\text{S}$ ),  $20 \pm 4.9 \mu\text{M}$  (ADPNP) and  $18 \pm 3.8 \mu\text{M}$  (ADPCP), respectively, indicating that the binding energy from additional interactions with the  $\gamma$ -phosphate is converted into conformational changes. The corresponding  $K_d$  values for the full-length reverse gyrase (rGyr\_fl) are virtually identical in the case of the mantADP, ADP and AMP complexes, and of the ATP analog  $\text{ATP}\gamma\text{S}$ , and 2- to 4-fold higher for the complexes with the nonhydrolyzable ATP analogs ADPNP and ADPCP (14). The similar  $K_d$  values confirm that all determinants for nucleotide binding are contained in the helicase-like domain. A summary of the  $K_d$  values for rGyr\_fl and rGyr\_hel is given in Table 1.

In a steady state ATPase assay, rGyr\_hel exhibits a low intrinsic ATPase activity (Figure 3). As with rGyr\_fl (14), the rate constant  $k_{\text{cat}}$  of ATP hydrolysis by rGyr\_hel is independent of the protein concentration ( $<10 \mu\text{M}$ , data not shown), consistent with a monomer as the active species. The dependence of the ATP hydrolysis rate on ATP concentration follows Michaelis–Menten behavior, with a  $k_{\text{cat}}$  for ATP hydrolysis of  $30 (\pm 2) \times 10^{-3} \text{ s}^{-1}$ , and a  $K_M$  value for ATP of  $77 \pm 23 \mu\text{M}$ . The corresponding values for reverse gyrase are very similar with a  $k_{\text{cat}}$  of  $20 (\pm 0.8) \times 10^{-3} \text{ s}^{-1}$  and a  $K_M$  of  $44 \pm 6 \mu\text{M}$  (14).

These results demonstrate that the nucleotide binding properties and the intrinsic ATPase activity of reverse

gyrase are a property of the helicase-like domain and are not significantly affected by the topoisomerase domain.

#### Stimulation of the rGyr\_hel and rGyr\_fl ATPase activities by nucleic acids

Reverse gyrases are DNA-stimulated ATPases (21). To investigate the effect of nucleic acid substrates on the ATPase activity of rGyr\_hel, steady state ATPase assays were performed in the presence of a 60-base ssDNA substrate, a 60 bp dsDNA, pUC18 plasmid DNA, and polyU-RNA at saturating ATP concentrations (Figure 4A). All substrates led to a significant acceleration of ATP hydrolysis. Saturating concentrations of ssDNA or linear dsDNA increased the  $k_{cat}$  by a factor of 40–50, with a slightly higher stimulation by dsDNA. The apparent  $K_M$  values are  $0.07 \pm 0.04 \mu\text{M}$  for ssDNA (corresponding to 4 μM in terms of bases) and  $0.18 \pm 0.03 \mu\text{M}$  for dsDNA (11 μM base pairs), respectively. In the presence of negatively supercoiled pUC18 plasmid, the  $k_{cat}$  value increased 22-fold ( $K_M$   $0.046 \pm 0.006 \mu\text{M}$ , corresponding to 124 μM base pairs).

Interestingly, polyU-RNA also stimulated the intrinsic ATPase activity of rGyr\_hel tremendously (~100-fold). With 25 μM (bases), the apparent  $K_M$  value for polyU-RNA was in the same range as for the pUC18 plasmid. PolyU-RNA binding might reflect nonspecific interactions with the negatively charged phosphoribose backbone, and we therefore repeated the steady state ATPase assay in the presence of increasing concentrations of heparin as a model for a negatively charged polymer. Indeed, heparin increased the  $k_{cat}$  of rGyr\_hel for ATP hydrolysis ~80-fold and thus had a comparable effect to the polyU-RNA. The  $K_M$  value for heparin was  $0.20 \pm 0.05 \mu\text{M}$  (8 μM monomeric units) and thus also similar to polyU.

To compare ATPase properties of the helicase-like domain with reverse gyrase, the steady state ATPase rates in the presence of ssDNA, dsDNA, pUC18 and

**Figure 4.** Effect of nucleic acid substrates on the steady state ATPase activity of rGyr\_hel and rGyr\_fl. (A and B) The effect of nucleic acid substrates on the ATPase rate at saturating (1 mM) ATP. (C and D) The ATP-dependence of the ATPase rate at saturating concentrations of nucleic acids. Substrates are indicated as follows: ssDNA (cyan, triangles), dsDNA (blue, inverted triangles), pUC18 (black, circles), polyU-RNA (orange, squares) and heparin (red, diamond). The open symbols in (C and D) indicate data in the absence of DNA. All steady state ATPase parameters are summarized in Tables 2 and 3. (A) Stimulation of the rGyr\_hel ATPase by nucleic acids and heparin. The ATPase activity is significantly stimulated by all substrates. (B) Stimulation of the rGyr\_fl ATPase by nucleic acids and heparin. The ATPase activity is significantly stimulated by all substrates, but in contrast to rGyr\_hel, no saturation is observed with pUC18. (C) Cooperativity between ATP and nucleic acid binding in rGyr\_hel. The steady state ATPase activity was measured as a function of ATP concentration in the presence of saturating concentrations of ssDNA (2  $\mu$ M), dsDNA (2.5  $\mu$ M), pUC18 (300 nM), polyU-RNA (1.5 mM monomers) and heparin (40  $\mu$ M monomers). (D) Cooperativity between ATP and nucleic acid binding in rGyr\_fl. The steady state ATPase activity was measured as a function of ATP concentration in the presence of saturating concentrations of ssDNA (2  $\mu$ M), dsDNA (5  $\mu$ M), pUC18 (300 nM), polyU-RNA (0.5 mM monomers) and heparin (60  $\mu$ M monomers).

polyU-RNA were also determined for rGyr\_fl (Figure 4B). As with rGyr\_hel, linear ssDNA and dsDNA showed a similar effect on the ATPase rate of rGyr\_fl. Importantly, the stimulation of the ATPase activity by ssDNA and dsDNA was only 7- to 8-fold. The ATPase rate of rGyr\_fl increases linearly up to a pUC18 concentration of 400 nM (1.1 mM bases), and saturation is not observed (14). In contrast to rGyr\_hel, pUC18 only showed a moderate stimulation of the rGyr\_fl ATPase rate (7-fold at 400 nM pUC18, compared to 22-fold at saturation for rGyr\_hel). As with rGyr\_hel, polyU-RNA showed the highest degree of stimulation of the reverse gyrase ATPase activity, with  $k_{cat}$  increased 25-fold ( $K_M$  30  $\mu$ M bases), and heparin showed a 6-fold stimulation ( $K_M$  6  $\mu$ M monomeric units). These data indicate that interactions with nonspecific substrates are similar for rGyr\_hel and rGyr\_fl. The  $k_{cat}$  values for rGyr\_fl and

rGyr\_hel in the absence and presence of nucleic acids and the apparent  $K_M$  values are summarized in Table 2.

Reverse gyrase is an enzyme unique to hyperthermophilic organisms, which thrive at temperatures of 75°C and higher. To investigate if the results from experiments at 37°C reflect the properties of reverse gyrase at its optimum temperature, the ATPase activity was determined at 75°C in the absence of DNA, and in the presence of ssDNA, dsDNA and pUC18 (Figure 5). In the absence of DNA, the ATPase activities of rGyr\_fl and rGyr\_hel are similar, with initial rates of 0.28  $\mu$ M s<sup>-1</sup> (rGyr\_hel) and 0.48  $\mu$ M s<sup>-1</sup> (rGyr\_fl). While we have determined the affinities for DNA substrates at 37°C and could therefore ensure saturating DNA concentrations in ATPase assays, a quantitative comparison of the ATPase stimulation at 75°C is difficult as the corresponding  $K_d$  values cannot easily be determined, and the DNA concentrations may not

**Table 2.** Steady state ATPase parameters for rGyr\_hel and rGyr\_fl, and the influence of nucleic acid substrates

	Nucleic acid	$k_{\text{cat}}$ ( $10^{-3} \text{ s}^{-1}$ )	$K_{\text{M,DNA}}$ ( $\mu\text{M}$ )	$K_{\text{M}}$ ( $\mu\text{M}$ base/bp)
rGyr_hel	–	$30 \pm 2$	NA	NA
	ssDNA	$1160 \pm 188$	$0.07 \pm 0.04$	$4.2 \pm 2.4$
	dsDNA	$1450 \pm 64$	$0.18 \pm 0.03$	$10.8 \pm 1.8$
	pUC18	$673 \pm 21$	$0.046 \pm 0.006$	$124 \pm 16$
	polyU-RNA	$3264 \pm 304$	NA	$25 \pm 10$
	Heparin	$2420 \pm 160$	$0.20 \pm 0.05$	$8.0 \pm 0.04$
rGyr_fl	–	$20 \pm 0.8$	NA	NA
	ssDNA	$160 \pm 6.7$	$0.45 \pm 0.06$	$27 \pm 4$
	dsDNA	$148 \pm 9.1$	$2.2 \pm 0.30$	$129 \pm 18$
	pUC18	No saturation for conc. <400 nM		
	polyU-RNA	$507 \pm 27$	NA	$30 \pm 7$
	Heparin	$120 \pm 10$	$0.15 \pm 0.06$	$6 \pm 2.4$

be saturating. In addition, the thermodynamic stability of the 60 bp duplex is limited ( $T_m = 70^\circ\text{C}$ ), and at  $75^\circ\text{C}$  more than 50% single strand are expected. Qualitatively, the rGyr\_hel ATPase activity at  $75^\circ\text{C}$  is stimulated to a similar extent by ssDNA and dsDNA at  $75^\circ\text{C}$ , and about 2-fold less by pUC18. Overall, the ATPase activity is increased only 3-fold by DNA substrates, compared to 50-fold at  $37^\circ\text{C}$ . The rGyr\_fl ATPase is most efficiently stimulated by ssDNA, and to a smaller extent by dsDNA or pUC18. As observed at  $37^\circ\text{C}$ , the overall stimulation is smaller for rGyr\_fl than for rGyr\_hel. Thus, the rGyr\_hel and rGyr\_fl ATPase activities at  $75^\circ\text{C}$  show the same response to DNA as at  $37^\circ\text{C}$ .

In summary, the basal ATP hydrolysis rates are very similar for rGyr\_hel and rGyr\_fl, confirming that all determinants for ATP binding and hydrolysis are confined to the helicase-like domain. The intrinsic ATPase of rGyr\_hel is efficiently stimulated by ssDNA, dsDNA and plasmid DNA. All substrates also stimulate the intrinsic ATP hydrolysis of rGyr\_fl, but generally to a lesser extent. These data point towards an inhibitory effect of the topoisomerase domain on the ATPase activity of the helicase-like domain in the presence of DNA substrates. The apparent  $K_{\text{M}}$  values for DNA are higher for rGyr\_fl than for rGyr\_hel. This effect seems to be slightly more pronounced for dsDNA, leading to a 5-fold higher apparent  $K_{\text{M}}$  for dsDNA over ssDNA for rGyr\_fl, compared to an only 2.5-fold difference for rGyr\_hel. Both enzymes thus appear to interact more tightly with ssDNA. Interestingly, the apparent  $K_{\text{M}}$  values for polyU-RNA and heparin are identical for rGyr\_fl and rGyr\_hel, indicating similar interactions with nonspecific substrates.

#### Coupling between DNA and ATP binding to rGyr\_hel and rGyr\_fl

The interaction of SF2 helicases with ATP and their DNA substrate is cooperative: ATP binding increases the affinity for the DNA substrate, and vice versa (13,22–24). To test whether any of the nucleic acid substrates shows such a cooperative effect on ATP binding to rGyr\_hel or rGyr\_fl, we determined the effect of DNA on  $K_{\text{M}}$  values for ATP by measuring the steady state ATPase rate with increasing

**Figure 5.** DNA-stimulated ATPase activity at  $75^\circ\text{C}$ . ATPase activity of rGyr\_hel (A) and rGyr\_fl (B) at  $75^\circ\text{C}$  in the absence of enzyme (open triangles), in the presence of  $1 \mu\text{M}$  enzyme without DNA (inverted triangles) and in the presence of ssDNA (100 nM, squares), dsDNA (100 nM, circles), or pUC18 (15 nM, triangles). The ATP concentration was 1 mM.

concentrations of ATP and saturating concentrations of the nucleic acid (Figure 4C and D). In all cases, the  $k_{\text{cat}}$  values are in good agreement with the values in the DNA-dependent experiments at saturating ATP concentrations (Table 2), confirming that saturation is reached in both series of experiments. In the presence of ssDNA, the apparent  $K_{\text{M,ATP}}$  value of rGyr\_hel is decreased 16-fold, demonstrating cooperative binding of ATP and ssDNA to rGyr\_hel. For dsDNA, this cooperativity is lower than for ssDNA, with  $K_{\text{M,ATP}}$  decreased 7-fold. The effect of pUC18 plasmid is intermediate, with a 10-fold decrease in the apparent  $K_{\text{M,ATP}}$ . Hence, all DNA substrates promote ATP binding to rGyr\_hel. PolyU-RNA and heparin only affect the apparent  $K_{\text{M,ATP}}$  slightly (1.8-fold and 2.5-fold, respectively) and thus do not show significant cooperativity. These data corroborate the notion that the stimulating effect of polyU-RNA and heparin on the ATPase activity of rGyr\_hel is due to a nonspecific interaction.

For rGyr<sub>fl</sub>, limited cooperativity of DNA and ATP binding was detected (Figure 4D). The reduction of the  $K_{M,ATP}$  was 3.8-fold for ssDNA and 2.8-fold for dsDNA. Hence, as for rGyr<sub>hel</sub>, the cooperativity with ATP binding is highest for ssDNA. However, the cooperativity of DNA and ATP binding to rGyr<sub>fl</sub> is smaller for ssDNA and dsDNA compared to rGyr<sub>hel</sub>. For pUC18, it was not possible to perform the experiment under saturating conditions. At 300 nM pUC18,  $K_{M,ATP}$  was reduced 2.8-fold. This is similar to the effect of linear dsDNA, whereas for rGyr<sub>hel</sub>, pUC18 shows intermediate cooperativity to ssDNA and dsDNA. However, a more pronounced effect of pUC18 on  $K_{M,ATP}$  for rGyr<sub>fl</sub> at higher plasmid concentrations cannot be excluded. Overall, rGyr<sub>fl</sub> shows cooperative interactions with DNA and ATP, but to a lesser extent than rGyr<sub>hel</sub>. PolyU-RNA and heparin had a negligible effect on ATP binding (1.4-fold and 1.2-fold, respectively), consistent with a nonspecific interaction. The  $k_{cat}$  and  $K_{M,ATP}$  values are summarized in Table 3.

Altogether, the interaction of rGyr<sub>hel</sub> and rGyr<sub>fl</sub> with polyU-RNA or heparin and ATP is noncooperative and most likely reflects a nonspecific interaction. Substantial cooperativity is observed for ssDNA, dsDNA or plasmid DNA and ATP binding to rGyr<sub>hel</sub>. rGyr<sub>fl</sub> also binds ssDNA or dsDNA and ATP cooperatively, but the effect of the DNA on  $K_{M,ATP}$  is only 3- to 4-fold, compared to 7- to 16-fold for rGyr<sub>hel</sub>. Again, this points towards a moderating effect of the topoisomerase domain on the helicase-like domain in full-length reverse gyrase.

#### Influence of the nucleotide state on DNA binding to rGyr<sub>hel</sub>

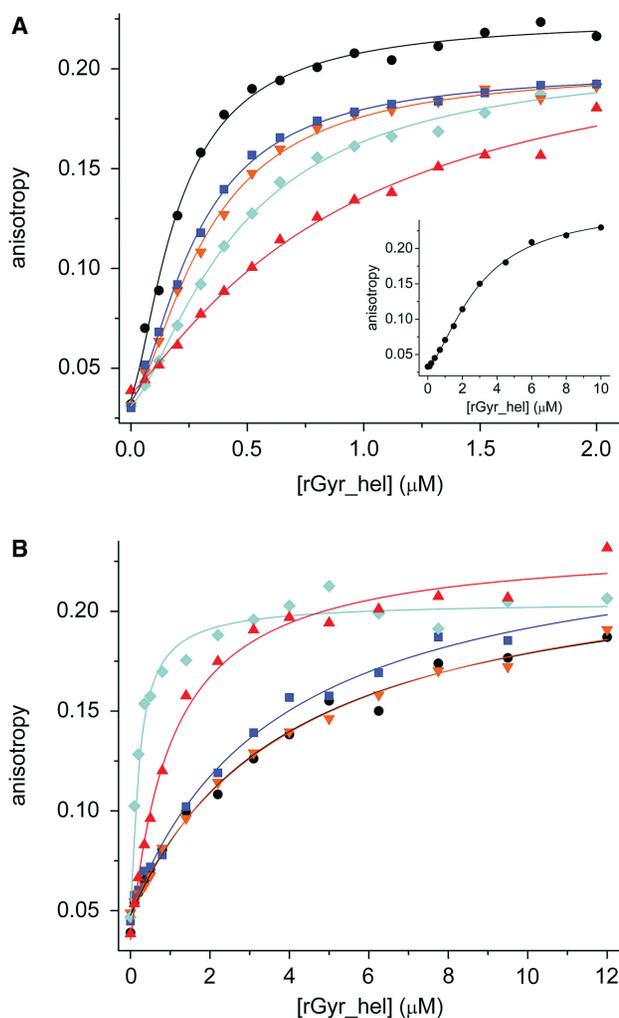

During their nucleotide cycle, SF2 helicases switch between low affinity and high affinity states for their nucleic acid substrate (22,25,26). We therefore investigated the influence of the nucleotide state of rGyr<sub>hel</sub> and rGyr<sub>fl</sub> on their interaction with DNA. To this end, the affinity of rGyr<sub>hel</sub> for nucleic acids was determined in fluorescence anisotropy titrations of a 5'-fluorescein-labeled 60-base ssDNA or a fluorescein-labeled 60 bp dsDNA in the absence of nucleotides, and in the presence of saturating concentrations of ADP, ADPCP, ADPNP and ATP $\gamma$ S (Figure 6, Table 4).

First, we characterized binding of ssDNA to rGyr<sub>hel</sub> (Figure 6A). The  $K_d$  value for the rGyr<sub>hel</sub>/ssDNA complex was  $0.20 \pm 0.03 \mu\text{M}$  in the absence of nucleotide, and varied only moderately with the nucleotide state. The non-hydrolyzable ATP analogs ADPNP and ATP $\gamma$ S showed the largest effect on ssDNA binding, with 3-fold (ADPNP) or 6-fold (ATP $\gamma$ S) increased  $K_d$  values, respectively, indicating that the affinity for ssDNA is slightly reduced in the ATP state of rGyr<sub>hel</sub>. The ADP state of rGyr<sub>hel</sub> binds ssDNA 1.5-fold less tightly than the nucleotide-free state, but 2- to 4-fold more tightly than the ATP-state (mimicked by ADPNP and ATP $\gamma$ S). ADPCP has a similar effect on ssDNA binding as ADP, suggesting that ADPCP is not a suitable mimic for ATP.

When the concentration of ssDNA in the titration with rGyr<sub>hel</sub> was increased to  $2 \mu\text{M}$ , a sigmoidal binding curve was obtained, indicating that more than one

<sup>a</sup>One-site.<sup>b</sup>Hill analysis.

rGyr\_hel molecule interacts with each ssDNA (Figure 6A, inset). The data were well-described by the Hill equation, with a Hill coefficient of  $1.6 \pm 0.1$ , and a  $K_d$  of  $2.9 \pm 0.1 \mu\text{M}$ . Analysis of all ssDNA titration curves with the Hill equation gave similar  $K_d$  values as the analysis with the one-site binding model (Table 4), and Hill coefficients of 1.2–1.6, indicating that the cooperativity is moderate.

Next, binding of rGyr\_hel to dsDNA was characterized (Figure 6B, Table 4). DsDNA was bound 10- to 20-fold less tightly by rGyr\_hel than ssDNA, consistent with the observed higher  $K_M$  value for dsDNA. The  $K_d$  value for dsDNA was  $\sim 3.9 \mu\text{M}$  in the absence of nucleotide, or in the presence of ADP or ADPCP. Only in the presence of ADPNP or ATP $\gamma$ S was a significant change observed: the  $K_d$  value of the dsDNA/rGyr\_hel complex was decreased 20-fold by ADPNP, or 4-fold by ATP $\gamma$ S. This decrease is consistent with ADPNP and ATP $\gamma$ S mimicking the ATP state. Overall, the ATP state of rGyr\_hel thus binds dsDNA 4- to 20-fold more tightly than the ADP state.

Comparison of DNA binding to different nucleotide states (Table 4) reveals that the nucleotide-free form of rGyr\_hel shows 20-fold higher affinity for ssDNA over dsDNA. In the ATP state, the affinity for ssDNA remains similar, but the dsDNA affinity increases compared to the nucleotide-free state. Thus, the ATP state exhibits similar affinities for ssDNA and dsDNA. In the ADP state, the affinity for ssDNA is similar to the nucleotide-free or ATP states, but the affinity for dsDNA is reduced compared to the ATP state. As a consequence, ssDNA binding is favored 11- to 13-fold in the ADP state. Hence, during the nucleotide cycle, rGyr\_hel does not discriminate between ssDNA and dsDNA prior to ATP hydrolysis, but will preferentially interact with ssDNA after hydrolysis.

Due to thermodynamic coupling, the observed increased affinity of the ATP state for dsDNA requires a reciprocal effect of DNA on ATP binding. Comparison with the steady state ATPase data (Figure 4A and C, Table 3) shows that this coupling is indeed present: the  $K_{M,ATP}$  of rGyr\_hel is decreased 7-fold

in the presence of dsDNA, which is in good agreement with the 4- to 20-fold increased dsDNA affinity in the ATP state of rGyr\_hel. The comparison for the ssDNA seems to be inconsistent: the ATP state of rGyr\_hel binds ssDNA 3- to 6-fold less tightly than the nucleotide-free form, but  $K_{M,ATP}$  is decreased 16-fold when ssDNA is bound. However, the observed differences most likely reflect differences of the ADPNP or ATP $\gamma$ S states compared to the ATP state. This is partly supported by experiments with a hydrolysis-deficient mutant (see below), where ATP binding does not reduce the ssDNA affinity.

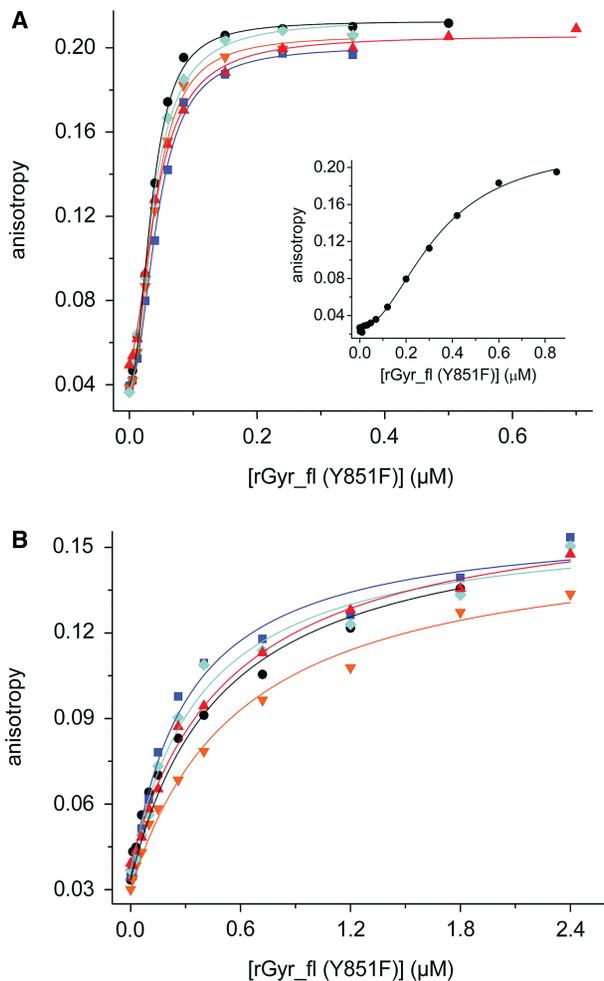

### Influence of the nucleotide state on DNA binding to rGyr\_fl

To test whether the helicase-like domain also acts as a nucleotide-dependent switch with different affinities for dsDNA in the ATP and ADP states in reverse gyrase, we performed DNA binding experiments with rGyr\_fl (Figure 7). Quantification of DNA binding to rGyr\_fl is complicated by the existence of several potential DNA binding sites that could be located in the helicase-like domain, in the cleft of the topoisomerase domain near the catalytic tyrosine, and possibly at the two putative zinc fingers. To ensure equilibrium conditions, we used the Y851F mutant of reverse gyrase in DNA binding experiments, which is deficient in covalent binding to the DNA.

Again, we first addressed binding of ssDNA to rGyr\_fl (Figure 7, Table 5). In a titration of the 60-base ssDNA with rGyr\_fl(Y851F), a sigmoidal dependence of the fluorescence anisotropy on the concentration of enzyme was observed (Figure 7A). The binding isotherm was well-described by the Hill equation, with a Hill coefficient of  $2.3 (\pm 0.2)$  and a  $K_d$  of  $36 \pm 1 \text{ nM}$  for nucleotide-free rGyr\_fl(Y851F), pointing towards cooperative binding of at least two reverse gyrase molecules to the DNA. To confirm the existence of cooperativity, the titration was repeated at 300 nM of ssDNA, where the sigmoidality became much more prominent (Figure 7A, inset). Description with the Hill equation yielded  $K_d = 0.33 \pm 0.02 \mu\text{M}$ , and  $n = 2.0 \pm 0.14$ . In the presence of saturating concentrations of ADP, ADPCP, ADPNP or ATP $\gamma$ S, binding isotherms for ssDNA to rGyr\_fl remained sigmoidal (Figure 7A), with Hill coefficients from  $1.8 \pm 0.10$  to  $2.1 \pm 0.16$ , again consistent with two reverse gyrase molecules binding to one ssDNA molecule.

Overall, rGyr\_fl binds ssDNA 6-fold more tightly than rGyr\_hel. In the presence of ADP, the interaction with ssDNA is only slightly affected, and it is virtually unchanged in the presence of nonhydrolyzable ATP analogs. Consequently, the affinity of rGyr\_fl for ssDNA is not significantly modulated by the nucleotide state.

Next, the interaction of rGyr\_fl(Y851F) with dsDNA was characterized (Figure 7, Table 5). Interestingly, the cooperativity was less pronounced for rGyr\_fl binding to dsDNA (Figure 7B). In this case, the binding isotherm could be described by a simple one-site model with a  $K_d$  of  $490 \pm 60 \text{ nM}$ . Thus, rGyr\_fl interacts 8-fold more tightly with dsDNA than rGyr\_hel. dsDNA bound to rGyr\_fl was displaced upon addition of an excess of

**Figure 7.** DNA binding and coupling to nucleotide binding (rGyr<sub>fl</sub>). Titration of DNA with rGyr<sub>fl</sub> in the absence of nucleotide (black circles), and in the presence of ADP (100 μM, blue squares), ADPCP (500 μM, orange, inverted triangles), ATP<sub>γ</sub>S (500 μM, red, triangles) and ADPNP (500 μM, cyan, diamonds). All  $K_d$  values and Hill coefficients are summarized in Table 5. (A) ssDNA (10 nM). The binding curves are described with the Hill equation. The inset shows the stoichiometric titration of 300 nM ssDNA with rGyr<sub>fl</sub>. (B) dsDNA (10 nM). The binding curves are described with a one-site binding model.

ssDNA (data not shown), demonstrating that both types of nucleic acids interact with the same binding site.

In the presence of nucleotides, the cooperativity of dsDNA binding appeared to increase slightly, as indicated by a slightly improved fit with the Hill equation. Hill coefficients varied between 0.7 and 1.7, consistent with a lower cooperativity compared to ssDNA (or a reduced number of binding sites). However, the experimental data were already reasonably well described with the one-site binding model. The presence of ADP, ADPNP, ADPCP or ATP<sub>γ</sub>S affects the affinity of rGyr<sub>fl</sub> for dsDNA <2-fold.

Comparison of DNA binding to different nucleotide states of rGyr<sub>fl</sub> (Table 5) shows that the nucleotide-free form binds dsDNA 14-fold less tightly than ssDNA. In the ATP or state, ssDNA or dsDNA binding are not affected. However, the ADP state binds dsDNA 2-fold more tightly than the nucleotide-free and the ATP states. In the nucleotide cycle, both the ATP and the ADP state bind ssDNA more tightly than dsDNA. The preference for ssDNA is slightly reduced after hydrolysis (from 10-fold in the ATP state to 4-fold in the ADP state). The small effect of nucleotides on DNA binding to rGyr<sub>fl</sub> is consistent with the small effect of ssDNA and dsDNA on ATP binding according to the steady state ATPase data (Figure 4B and D, Table 3).

In summary, the ATP state of rGyr<sub>hel</sub> binds ssDNA and dsDNA with equal affinities, whereas the ADP state interacts preferentially with ssDNA. rGyr<sub>fl</sub> binds DNA ~10-fold more tightly than rGyr<sub>hel</sub>, but the differences between the nucleotide states are far less pronounced. Both the ATP and the ADP states bind preferentially to ssDNA.

#### DNA binding to different nucleotide states of a hydrolysis-deficient mutant of rGyr<sub>fl</sub> and rGyr<sub>hel</sub>

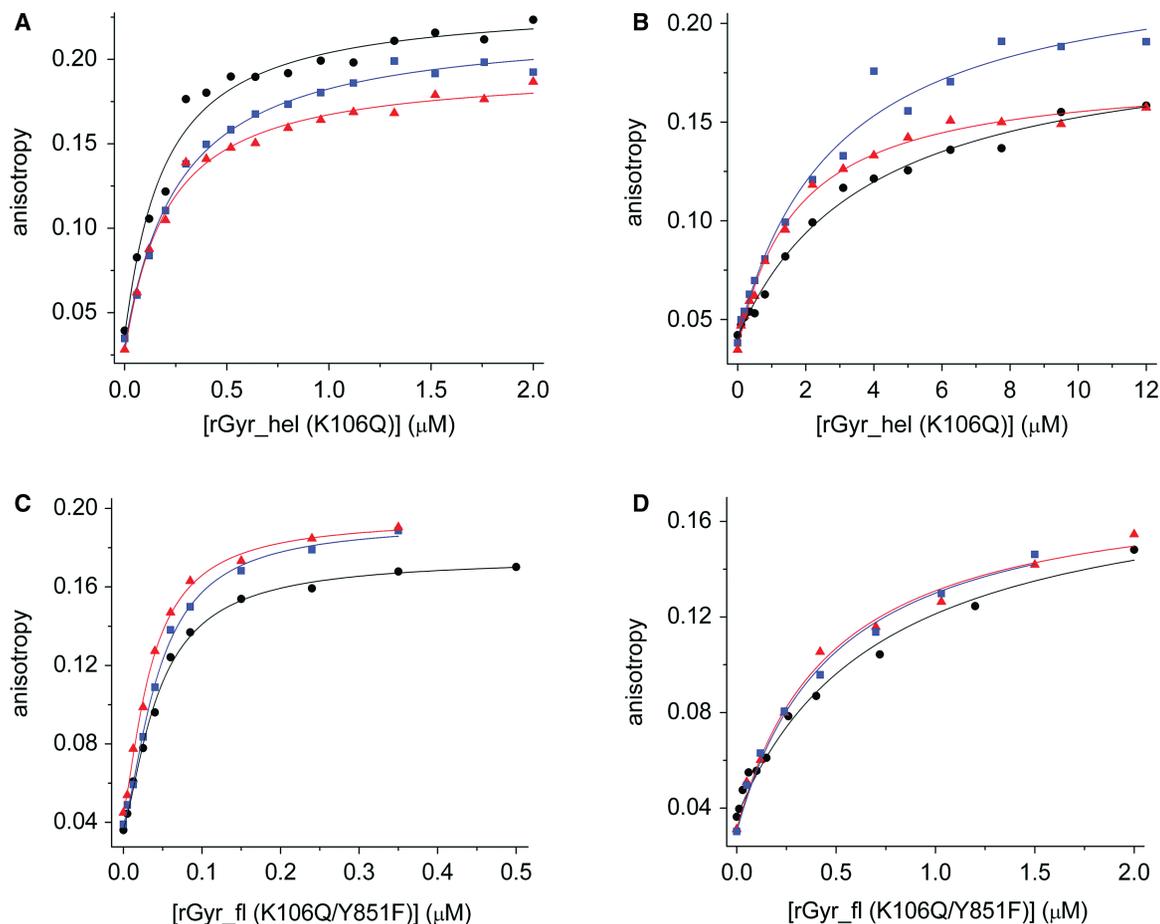

As complexes with the nonhydrolyzable ATP analogs might not perfectly mimic the ATP states, we analyzed the effect of nucleotides on the interaction with DNA using hydrolysis-deficient mutants of rGyr<sub>hel</sub> and rGyr<sub>fl</sub>. A conserved lysine in the Walker A motif of

<sup>b</sup>Hill analysis.

**Figure 8.** Binding of ssDNA and dsDNA to rGyr\_hel(K106Q) and rGyr\_fl(K106Q/Y851F). Titrations of ssDNA (A, C) and dsDNA (B, D) with rGyr\_hel(K106Q) (A, B) or rGyr\_fl(K106Q/Y851F) (C, D) in the absence of nucleotide (black, circles), and in the presence of ADP (2 mM, blue, squares) or ATP (4 mM, red, triangles). The DNA concentration was 25 nM in (A and B), and 10 nM in (C and D). The  $K_d$  values are summarized in Table 5.

ATPases contacts the  $\beta$ - and  $\gamma$ -phosphates of ATP, and stabilizes negative charges during ATP hydrolysis. In the rGyr\_fl(K106Q) mutant, ATP hydrolysis is abolished, but nucleotides are still bound, albeit with reduced affinity (14). The rGyr\_fl(K106Q/Y851F) double mutant was created to stably generate ATP and ADP states of reverse gyrase that do not covalently bind to DNA. The absence of ATP hydrolysis was confirmed, and the  $K_d$  values of the nucleotide complexes were determined to be  $22 \pm 2 \mu\text{M}$  (mantADP),  $36 \pm 5 \mu\text{M}$  (ADP) and  $98 \pm 12 \mu\text{M}$  (ATP) in equilibrium titrations (Table 1). Overall, nucleotide binding to rGyr\_fl(K106Q/Y851F) is reduced  $\sim 20$ -fold compared to wild-type.

The DNA binding properties of this ATP-hydrolysis- and DNA-cleavage-deficient mutant were studied using the 60-base ssDNA and 60 bp dsDNA as a substrate (Figure 8, Table 5). ssDNA was bound independent of the nucleotide state, with  $K_d$  values of  $44 \pm 3 \text{ nM}$  (no nucleotide),  $44 \pm 2 \text{ nM}$  (ADP state) and  $35 \pm 2 \text{ nM}$  (ATP state).  $K_d$  values for the corresponding dsDNA complexes were higher, consistent with the lower affinity of rGyr\_fl for dsDNA. Similar to ssDNA binding, interaction of rGyr\_fl(K106Q/Y851F) with dsDNA is independent of the nucleotide state. The  $K_d$  values of the dsDNA

complexes are  $0.71 \pm 0.11 \mu\text{M}$  (no nucleotide),  $0.46 \pm 0.07 \mu\text{M}$  (ADP state) and  $0.49 \pm 0.09 \mu\text{M}$  (ATP state). Consistent with the wild-type data, the hydrolysis-deficient mutant of rGyr\_fl thus shows  $\sim 10$ -fold tighter binding of ssDNA to all nucleotide states.

The data for the wild-type enzyme and nonhydrolyzable ATP analogs (Figure 7, Table 5) support a slightly decreased preference for ssDNA after hydrolysis. The increased preference for ssDNA in the ADP state of rGyr\_fl(K106Q/Y851F) results from a 2-fold increased  $K_d$  of  $0.46 \mu\text{M}$  for the dsDNA complex, compared to a  $K_d$  of  $0.25 \mu\text{M}$  for rGyr\_fl(Y851F), and suggests differences between the ADP state of wild-type rGyr\_fl and the K106Q/Y851F mutant. Previous work already pointed towards such a difference: Reverse gyrase relaxes negatively supercoiled DNA in the presence of ADP, whereas the K106Q mutant lacks such a relaxation activity (14). Most likely, lysine 106 functions as a nucleotide sensor that triggers an ADP-dependent conformational change that is required for relaxation. If this conformational change is absent in the K106Q mutant, the ADP state will be different, leading to different DNA binding properties.

To compare the DNA binding properties of the nucleotide states of rGyr\_hel with rGyr\_fl, the corresponding

K106Q mutation in the Walker A motif of rGyr\_hel was introduced, and the absence of hydrolysis was confirmed (data not shown). Fluorescence equilibrium titrations revealed a  $K_d$  value for the mantADP complex of  $67 \pm 5 \mu\text{M}$ , and  $150 \pm 85 \mu\text{M}$  and  $570 \pm 300 \mu\text{M}$  for the ADP and ATP complexes, respectively (Table 1). Thus, the nucleotide affinity of the K106Q mutant of rGyr\_hel is  $\sim 60$ -fold reduced compared to the wild-type. This effect is more pronounced than for rGyr\_fl (20-fold).

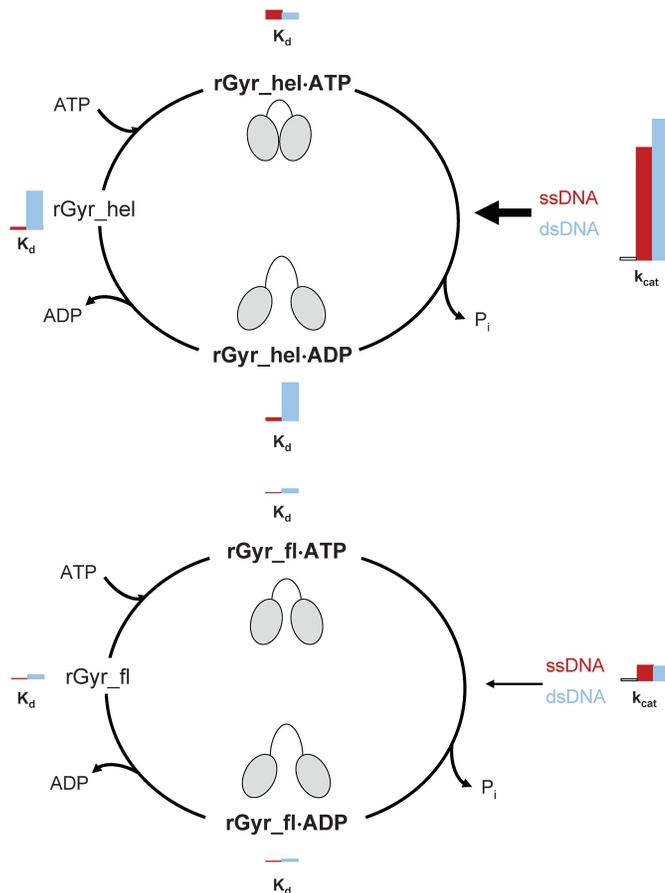

rGyr\_hel(K106Q) binds ssDNA 20-fold more tightly than dsDNA ( $K_d = 0.18 \pm 0.03$  and  $3.8 \pm 0.6 \mu\text{M}$ , respectively). In the presence of ADP or ATP, ssDNA binding is not significantly affected, and dsDNA binding is only slightly increased (ADP: 1.3-fold,  $K_d = 2.9 \pm 0.6 \mu\text{M}$ ; ATP: 2.2-fold,  $K_d = 1.7 \pm 0.2 \mu\text{M}$ ). As a consequence, ssDNA interacts more tightly than dsDNA with both nucleotide states (12-fold, ADP state; 9-fold, ATP state), implying a slightly stronger preference for ssDNA after ATP hydrolysis. Similarly, the data from wild-type rGyr\_hel suggest a stronger interaction with ssDNA after ATP hydrolysis. However, wild-type rGyr\_hel in complex with nonhydrolyzable ATP analogs binds ssDNA and dsDNA with similar affinities, while the ATP state of rGyr\_hel(K106Q) interacts 9-fold more tightly with ssDNA. This discrepancy arises from a reduced affinity of the rGyr\_hel(K106Q) ATP state for dsDNA compared to the ADPNP or ATP $\gamma$ S state of the wild-type rGyr\_hel (Figure 6, Table 4), suggesting structural differences between the ATP state of rGyr\_hel(K106Q) and the corresponding complexes of wild-type with nonhydrolyzable analogs.

Altogether, rGyr\_hel shows similar affinities for ssDNA and dsDNA in the ATP state, and a 10-fold preference for ssDNA in the ADP state due to a decrease in dsDNA affinity. Thus, the helicase domain switches from a 'high affinity' state with respect to dsDNA to a 'low affinity' state upon ATP hydrolysis, and back to the 'high affinity' state after nucleotide exchange, while the ssDNA affinity remains constant. In rGyr\_fl, both nucleotide states show a preference for ssDNA, indicating that the switch to the 'low affinity' state for dsDNA upon ATP hydrolysis is suppressed in the full-length enzyme. Figure 9 summarizes the properties of rGyr\_hel and rGyr\_fl. The K106Q mutants of rGyr\_hel and rGyr\_fl show similar DNA preferences, with a 10-fold higher affinity for ssDNA compared to dsDNA in both nucleotide states. These results argue for a critical role of lysine 106 as a nucleotide sensor in the helicase domain, and for inter-domain communication between the helicase-like and the topoisomerase domains.

## DISCUSSION

### The helicase-like domain confers nucleotide-dependent DNA binding to reverse gyrase

We have shown here that the nucleotide binding properties of reverse gyrase are a function of the N-terminal helicase-like domain. Nucleotide affinities and ATP hydrolysis rates are virtually identical for the isolated helicase-like domain and for the full-length enzyme in the

**Figure 9.** Overview of the nucleotide cycle of rGyr\_hel and rGyr\_fl. The  $K_d$  values of the nucleotide states for ssDNA (red) and dsDNA (blue) are displayed as bars with a size proportional to their value. Analogously, a red bar denotes the  $k_{cat}$  value in the presence of ssDNA, a blue bar corresponds to the  $k_{cat}$  value in the presence of dsDNA. For reference, an additional bar represents the intrinsic  $k_{cat}$  in the absence of DNA. A cartoon indicates possible conformations of the helicase-like domain in the different nucleotide states of rGyr\_hel and rGyr\_fl. rGyr\_hel (upper panel) shows similar affinities for ssDNA and dsDNA in the ATP state, and a preference for ssDNA in the ADP state due to a decrease in dsDNA affinity. This corresponds to a switch from a 'high affinity' state with respect to dsDNA to a 'low affinity' state upon ATP hydrolysis. Both dsDNA and ssDNA efficiently stimulate ATP hydrolysis (arrow). Most likely, the helicase-like domain switches between a closed conformation (cartoon) in the presence of DNA and ATP that hydrolyzes ATP efficiently, and an open conformation in the ADP state, as observed for SF2 helicases. In rGyr\_fl (lower panel), both nucleotide states show a preference for ssDNA, indicating that the switch to the 'low affinity' state for dsDNA upon ATP hydrolysis is suppressed in the full-length enzyme. The ATPase stimulation by DNA is 10-fold smaller than in rGyr\_hel. Possibly, steric hindrance by the topoisomerase domain prevents a complete closure of the helicase-like domain (cartoon) in the context of full-length reverse gyrase. The progression through the nucleotide cycle with moderate velocity may be required for efficient coupling of ATP hydrolysis and positive supercoiling.

absence of nucleic acids. Thus, all determinants for nucleotide binding and hydrolysis are contained within the helicase-like domain, and its characteristics are unaltered in the context of reverse gyrase. The similar ATPase rates suggest that the conformations of the helicase-like domains are similar, indicating that the arrangement of

the catalytic residues in the isolated helicase-like domain and in context of reverse gyrase are the same.

Our results demonstrate that the helicase-like domain mediates nucleotide-dependent interactions of reverse gyrase with ssDNA and dsDNA, and with plasmid DNA. In the ATP state, dsDNA and ssDNA are bound with similar affinities, whereas after ATP hydrolysis, ssDNA is preferentially bound. The DNA substrates influence the rate of switching between these states by stimulating the intrinsic ATPase activity of the helicase-like domain. Thus, the helicase-like domain is a module that confers nucleotide-dependent DNA binding to reverse gyrase. The topoisomerase domain has no influence on nucleotide binding and hydrolysis by the helicase-like domain in the absence of DNA, but modulates the ATPase properties in the presence of DNA. In the context of reverse gyrase, the ATPase activity of the helicase-like domain is still stimulated by the same DNA substrates, but to a much lesser extent. The DNA-stimulated ATPase activity of reverse gyrase is 10-fold lower than that in the isolated domain, demonstrating that the activity of the helicase-like domain is strongly suppressed by the topoisomerase domain.

The nucleic acid-stimulated ATPase activity of SF2 helicases results from a conformational change upon binding of both ligands that leads to a closure of the cleft between the two helicase subdomains. In this closed conformation, the catalytic residues are correctly positioned for efficient ATP hydrolysis. It has been proposed that such a conformational change in the helicase-like domain initiates supercoiling by reverse gyrase (10,14). The observed similar ATPase activities of the helicase-like domain and reverse gyrase suggest a similar open conformation of the helicase in both enzymes (Figure 9). In the presence of DNA, the isolated helicase-like domain adopts a closed conformation that rapidly hydrolyzes ATP. Possibly, in full-length reverse gyrase the topoisomerase domain provides a steric hindrance for the conformational change in the helicase-like domain. This steric hindrance may confine the helicase-like domain to a more open form even in the presence of nucleic acids, and consequently to less efficient ATP hydrolysis by reverse gyrase compared to the isolated helicase-like domain. A restriction of this conformational change by the topoisomerase domain would also readily explain the lower cooperativity between ATP and nucleotide binding in rGyr<sub>fl</sub>.

#### **Inter-domain communication in reverse gyrase: DNA binding and ATPase stimulation**

The helicase-like domain and reverse gyrase interact more tightly with ssDNA than with dsDNA. This preference for ssDNA is reminiscent of other type I DNA topoisomerases (27). The high affinity of reverse gyrase for ssDNA may allow for sensing of single-stranded regions (5), and lead to stabilization of these regions for strand cleavage and the subsequent strand-passage reaction during catalysis. It has been shown previously that the presence of single-stranded regions in the DNA substrate favors positive supercoiling by reverse gyrase (5). Reverse gyrase contains several potential interaction sites for nucleic acids, located in the helicase-like domain, or in a cleft close to

the catalytic tyrosine. In addition, the latch region may contact DNA (10,12), and a transient interaction of the putative zinc fingers with the DNA during supercoiling has been proposed (10). However, nucleic acid binding to these different interaction sites of reverse gyrase has not been characterized in detail. By using the Y851F mutant of reverse gyrase in DNA binding studies, we excluded the covalent binding of DNA *via* the catalytic tyrosine. In general, the DNA affinity of reverse gyrase is about 10-fold higher than that for the helicase-like domain. This increased affinity could either reflect tight DNA binding to the helicase-like domain in reverse gyrase, or point towards simultaneous interactions of DNA with the topoisomerase domain that increase the overall affinity. Clearly, a more detailed analysis of DNA binding to reverse gyrase would be required to further understand the relation between DNA binding to different sites and stimulation of ATP hydrolysis. However, in this context it is important to note that the cooperativity observed for ssDNA binding does not reflect two DNA molecules binding to one molecule of reverse gyrase (as would be possible if one ssDNA molecule interacts with the helicase-like domain and one with the topoisomerase domain). Instead, the data is consistent with the interaction of two reverse gyrase molecules with one ssDNA molecule, pointing towards a possible interaction between reverse gyrase molecules on the same substrate DNA. The fact that this cooperative effect is more pronounced for the full-length enzyme than for the isolated helicase-like domain, and only observed for ssDNA but not for dsDNA, suggests a functional role of this protein-protein interaction during the supercoiling reaction.

#### **Is the ATPase activity of the helicase-like domain modulated to achieve optimal coupling of ATP hydrolysis to positive supercoiling?**

Our results demonstrate that the helicase-like domain of reverse gyrase meets most criteria for a bona fide helicase: it has a DNA-dependent ATPase activity, and the nucleotide-state determines its affinity for ssDNA and dsDNA. However, as already reported for other reverse gyrase homologs, we did not detect DNA unwinding activity for the helicase-like domain of *T. maritima* reverse gyrase (data not shown). Altogether, the helicase-like domain of reverse gyrase acts as a nucleotide-dependent switch reminiscent of the nonprocessive DEAD box helicases that constitute a subfamily of SF2 helicases (28).

Helicase domains frequently occur in conjunction with additional domains that mediate substrate specificity or the interaction with protein partners, or regulate helicase activity (29–33). For instance, the DEAD box helicase RIG-I consists of a helicase domain and two N-terminal caspase activation and recruitment domains that connect the helicase function to the caspase signaling pathway, and these additional domains inhibit the RIG-I helicase activity (33). Conversely, the internal helicase domain of dicer inhibits its RNase activity (32), demonstrating that the domains can mutually influence their respective activities. Likewise, the ATPase activity of the helicase-like

domain in the presence of DNA is attenuated in the context of reverse gyrase, and the differences in nucleic acid affinities of the nucleotide states are smaller (Figure 9). A repression of relaxation activity of the topoisomerase domain in the absence of nucleotides by the helicase-like domain, mediated by the latch region (11,12), has been demonstrated earlier. The inhibition of the helicase-like domain we describe here seems to be the reciprocal effect. Deletion of the latch region increases the ATPase activity of reverse gyrase in the presence of ssDNA (11), suggesting a simultaneous role of the latch for the inhibitory effect of the topoisomerase domain on the helicase-like domain. Both effects emphasize the importance of communication between the reverse gyrase domains. The fact that the differences between switching of the helicase-like domain and reverse gyrase are mostly lost in the K106Q mutants suggests a critical contribution of the Walker A motif to inter-domain communication.

As a consequence of the inhibitory effect of the topoisomerase domain on the helicase-like domain in reverse gyrase, the progression through the nucleotide cycle in the presence of DNA is strongly decelerated. DNA supercoiling is a complex multi-step process, and the current model of DNA supercoiling by type IA topoisomerases such as reverse gyrase involves DNA cleavage, strand passage and re-ligation of the cleaved strand. This reaction will most likely require substantial conformational changes in reverse gyrase, and supercoiling is therefore an intrinsically slow process. Thus, a rapid cycling between the nucleotide states may not be necessary or could even be detrimental for supercoiling. Instead, the precise coordination of ATP hydrolysis and supercoiling may require matching rates for both processes, and hence a moderate ATP turnover. The inhibitory effect of the topoisomerase domain on the helicase-like domain emphasizes the role of inter-domain communication for efficient coupling between ATP hydrolysis and positive DNA supercoiling by reverse gyrase.

## SUPPLEMENTARY DATA

Supplementary Data are available at NAR Online.

## ACKNOWLEDGEMENTS

We thank Manuel Hilbert for performing the unwinding experiment with rGyr\_hel and Markus Rudolph for discussions.

## FUNDING

VolkswagenStiftung; Swiss National Science Foundation. Funding for open access charge: Swiss National Science Foundation.
