

# Basic Object-Oriented Programming in Java

Originals of Slides and Source Code for Examples:  
<http://courses.coreservlets.com/Course-Materials/java5.html>

**Customized Java EE Training:** <http://courses.coreservlets.com/>  
Servlets, JSP, JSF 2.0, Struts, Ajax, GWT 2.0, Spring, Hibernate, SOAP & RESTful Web Services, Java 6.  
Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

2

**For live Java EE training, please see training courses  
at <http://courses.coreservlets.com/>.**

Servlets, JSP, Struts, JSF 1.x, JSF 2.0, Ajax (with jQuery, Dojo, Prototype, Ext-JS, Google Closure, etc.), GWT 2.0 (with GXT), Java 5, Java 6, SOAP-based and RESTful Web Services, Spring, Hibernate/JPA, and customized combinations of topics.

**Taught by the author of *Core Servlets and JSP*, *More Servlets and JSP*, and this tutorial. Available at public venues, or customized versions can be held on-site at your organization. Contact [hall@coreservlets.com](mailto:hall@coreservlets.com) for details.**

# Agenda

- **Similarities and differences between Java and C++**
- **Object-oriented nomenclature and conventions**
- **Instance variables (fields)**
- **Methods (member functions)**
- **Constructors**

"Object-oriented programming is an exceptionally bad idea which could only have originated in California." -- Edsger Dijkstra, 1972 Turing Award winner.

4

# Basics

**Customized Java EE Training:** <http://courses.coreservlets.com/>  
Servlets, JSP, JSF 2.0, Struts, Ajax, GWT 2.0, Spring, Hibernate, SOAP & RESTful Web Services, Java 6.  
Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

5

# Object-Oriented Programming in Java

- **Similarities with C++**
  - User-defined classes can be used like built-in types.
  - Basic syntax
- **Differences from C++**
  - Methods (member functions) are the only function type
  - Object is the topmost ancestor for all classes
  - All methods use the run-time, not compile-time, types (i.e. all Java methods are like C++ virtual functions)
  - The types of all objects are known at run-time
  - All objects are allocated on the heap (always safe to return objects from methods)
  - Single inheritance only
- **Comparisons to C#**
  - C# very similar to Java in OOP. For details, see [http://www.harding.edu/fmccown/java1\\_5\\_csharp\\_comparison.html](http://www.harding.edu/fmccown/java1_5_csharp_comparison.html)

6

## Object-Oriented Nomenclature

- **“Class” means a category of things**
  - A class name can be used in Java as the type of a field or local variable or as the return type of a function (method)
- **“Object” means a particular item that belongs to a class**
  - Also called an “instance”
- **Example**

```
String s1 = "Hello";
```

  - Here, String is the class, and the variable s1 and the value "Hello" are objects (or “instances of the String class”)

7

# Instance Variables

Customized Java EE Training: <http://courses.coreservlets.com/>  
Servlets, JSP, JSF 2.0, Struts, Ajax, GWT 2.0, Spring, Hibernate, SOAP & RESTful Web Services, Java 6.  
Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

8

## Overview

- **Definition**

- Data that is stored inside an object. “Instance variables” can also be called “data members” or “fields”.

- **Syntax**

```
public class MyClass {  
    public SomeType field1, field2;  
}
```

In any class that also has methods, it is almost always better to declare instance variables private. We will show how and why in the next tutorial section.

- **Motivation**

- Lets an object have persistent values.
  - It is often said that in OOP, objects have three characteristics: state, behavior, and identity. The instance variables provide the state.

9

# Ship Example 1: Instance Variables

```
public class Ship1 {                                (In Ship1.java)
    public double x, y, speed, direction;
    public String name;
}
```

```
public class Test1 {                                (In Test1.java)
    public static void main(String[] args) {
        Ship1 s1 = new Ship1();
        s1.x = 0.0;
        s1.y = 0.0;
        s1.speed = 1.0;
        s1.direction = 0.0;    // East
        s1.name = "Ship1";
        Ship1 s2 = new Ship1();
        s2.x = 0.0;
        s2.y = 0.0;
        s2.speed = 2.0;
        s2.direction = 135.0; // Northwest
        s2.name = "Ship2";
        ...
    }
}
```

10

## Instance Variables: Example (Continued)

```
...
s1.x = s1.x + s1.speed
        * Math.cos(s1.direction * Math.PI / 180.0);
s1.y = s1.y + s1.speed
        * Math.sin(s1.direction * Math.PI / 180.0);
s2.x = s2.x + s2.speed
        * Math.cos(s2.direction * Math.PI / 180.0);
s2.y = s2.y + s2.speed
        * Math.sin(s2.direction * Math.PI / 180.0);
System.out.println(s1.name + " is at ("
        + s1.x + "," + s1.y + ").");
System.out.println(s2.name + " is at ("
        + s2.x + "," + s2.y + ").");
}
}
```

11

# Instance Variables: Results

- **Compiling and running in Eclipse**

- Save Test1.java
- R-click, Run As → Java Application

- **Compiling and running manually**

```
DOS> javac Test1.java
```

```
DOS> java Test1
```

**Output:**

```
Ship1 is at (1,0) .
```

```
Ship2 is at (-1.41421,1.41421) .
```

# Example 1: Major Points

- **Java naming conventions**
- **Format of class definitions**
- **Creating classes with “new”**
- **Accessing fields with  
“variableName.fieldName”**

# Java Naming Conventions

- **Start classes with uppercase letters**

- Constructors (discussed later in this section) must exactly match class name, so they also start with uppercase letters

```
public class MyClass {  
    ...  
}
```

14

# Java Naming Conventions

- **Start other things with lowercase letters**

- Instance vars, local vars, methods, parameters to methods

```
public class MyClass {  
    public String firstName, lastName;  
  
    public String fullName() {  
        String name =  
            firstName + " " + lastName;  
        return(name);  
    }  
}
```

15

# Objects and References

- Once a class is defined, you can declare variables (object reference) of that type

```
Ship s1, s2;  
Point start;  
Color blue;
```

- Object references are initially **null**
  - The **null** value is a distinct type in Java and is not equal to zero
  - A primitive data type (e.g., int) cannot be cast to an object (e.g., String), but there are some conversion wrappers
- The **new** operator is required to explicitly create the object that is referenced

```
ClassName variableName = new ClassName();
```

16

# Accessing Instance Variables

- Use a dot between the variable name and the field  
`variableName.fieldName`

- Example

- For example, Java has a built-in class called `Point` that has `x` and `y` fields

```
Point p = new Point(2, 3); // Build a Point object  
int xSquared = p.x * p.x;  // xSquared is 4  
int xPlusY = p.x + p.y;    // xPlusY is 5  
p.x = 7;  
xSquared = p.x * p.x;      // Now xSquared is 49
```

- Exceptions

- Methods can access fields of current object without `varName`
  - See upcoming method examples
- It is conventional to make all instance variables private
  - In which case outside code can't access them directly

17

# Methods

Customized Java EE Training: <http://courses.coreservlets.com/>  
Servlets, JSP, JSF 2.0, Struts, Ajax, GWT 2.0, Spring, Hibernate, SOAP & RESTful Web Services, Java 6.  
Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

18

## Overview

- **Definition**
  - Functions that are defined inside a class. “Methods” can also be called “member functions”.
- **Syntax**

```
public class MyClass {  
    public myMethod(...) { ... }  
}
```

If you want code that uses your class to access the method, make it public. If your method is called only by other methods in the same class, make it private.
- **Motivation**
  - Lets an object calculate values or do operations, usually based on its current state (instance variables).
    - It is often said that in OOP, objects have three characteristics: state, behavior, and identity. The methods provide the behavior.

19

## Ship Example 2: Methods

```
public class Ship2 {                                     (In Ship2.java)
    public double x=0.0, y=0.0, speed=1.0, direction=0.0;
    public String name = "UnnamedShip";

    private double degreesToRadians(double degrees) {
        return(degrees * Math.PI / 180.0);
    }

    public void move() {
        double angle = degreesToRadians(direction);
        x = x + speed * Math.cos(angle);
        y = y + speed * Math.sin(angle);
    }

    public void printLocation() {
        System.out.println(name + " is at ("
                               + x + ", " + y + ").");
    }
}
```

20

## Methods (Continued)

```
public class Test2 {                                     (In Test2.java)
    public static void main(String[] args) {
        Ship2 s1 = new Ship2();
        s1.name = "Ship1";
        Ship2 s2 = new Ship2();
        s2.direction = 135.0; // Northwest
        s2.speed = 2.0;
        s2.name = "Ship2";
        s1.move();
        s2.move();
        s1.printLocation();
        s2.printLocation();
    }
}
```

- **Compiling and Running: (R-click, Run As in Eclipse)**

```
javac Test2.java
java Test2
```

- **Output:**

```
Ship1 is at (1,0).
Ship2 is at (-1.41421,1.41421).
```

21

## Example 2: Major Points

- Format of method definitions
- Methods that access local fields
- Calling methods
- Static methods
- Default values for fields
- public/private distinction

22

## Defining Methods (Functions Inside Classes)

- Basic method declaration:

```
public ReturnType methodName(Type1 arg1,  
                             Type2 arg2, ...) {  
    ...  
    return(somethingOfReturnType);  
}
```

- Exception to this format: if you declare the return type as **void**
  - This special syntax that means “this method isn’t going to return a value – it is just going to do some side effect like printing on the screen”
  - In such a case you do not need (in fact, are not permitted), a **return** statement that includes a value to be returned

23

# Examples of Defining Methods

- **Here are two examples:**
  - The first squares an integer
  - The second returns the faster of two **Ship** objects, assuming that a class called **Ship** has been defined that has a field named **speed**

```
// Example function call:  
//   int val = square(7);  
  
public int square(int x) {  
    return(x*x);  
}  
  
// Example function call:  
//   Ship faster = fasterShip(someShip, someOtherShip);  
  
public Ship fasterShip(Ship ship1, Ship ship2) {  
    if (ship1.speed > ship2.speed) {  
        return(ship1);  
    } else {  
        return(ship2);  
    }  
}
```

24

# Calling Methods

- **The term “method” means “function associated with an object” (I.e., “member function”)**

- The usual way that you call a method is by doing the following:

```
variableName.methodName(argumentsToMethod);
```

- **For example, the built-in `String` class has a method called `toUpperCase` that returns an uppercase variation of a `String`**

- This method doesn't take any arguments, so you just put empty parentheses after the function (method) name.

```
String s1 = "Hello";  
String s2 = s1.toUpperCase(); // s2 is now "HELLO"
```

25

# Accessing External and Internal Methods

- **Accessing methods in other classes**
  - Get an object that refers to instance of other class
    - `Ship s = new Ship();`
  - Call method on that object
    - `s.move();`
- **Accessing instance vars in same class**
  - Call method directly (no variable name and dot in front)
    - `move();`
    - `double d = degreesToRadians();`
      - For local methods, you can use a variable name if you want, and Java automatically defines one called “this” for that purpose. See constructors section.
- **Accessing static methods**
  - Use `ClassName.methodName(args)`
    - `double d = Math.cos(Math.PI/2);`

26

# Calling Methods (Continued)

- **There are two exceptions to requiring a variable name for a method call**
  - Calling a method defined inside the current class definition
    - Use “`methodName(args)`” instead of “`varName.methodName(args)`”
  - Functions (methods) that are declared “`static`”
    - Use “`ClassName.methodName(args)`”
- **Calling a method of the current class**
  - You don’t need the variable name and the dot
  - For example, a `Ship` class might define a method called `degreesToRadians`, then, within another function in the same class definition, do this:  

```
double angle = degreesToRadians(direction);
```

    - No variable name and dot is required in front of `degreesToRadians` since it is defined in the same class as the method that is calling it

27

# Static Methods

- **Also “class methods” (vs. “instance methods”)**
  - Static functions do not access any non-static methods or fields within their class and are almost like global functions in other languages
- **You call a static method through the class name**  
`ClassName.functionName(arguments);`
  - For example, the **Math** class has a static method called **cos** that expects a **double** precision number as an argument
    - So you can call **Math.cos(3.5)** without ever having any object (instance) of the **Math** class
- **Note on the main method**
  - Since the system calls **main** without first creating an object, **static** methods are the only type of methods that **main** can call directly (i.e. without building an object and calling the method of that object)

28

# Method Visibility

- **public/private distinction**
  - A declaration of **private** means that “outside” methods can’t call it – only methods within the same class can
    - Thus, for example, the **main** method of the **Test2** class could not have done  
`double x = s1.degreesToRadians(2.2);`
      - Attempting to do so would have resulted in an error at compile time
  - Only say **public** for methods that you *want to guarantee your class will make available to users*
  - You are free to change or eliminate private methods without telling users of your class
- **private instance variables**
  - In next lecture, we will see that you almost always make instance vars private and use methods to access them

29

# Declaring Variables in Methods

- **Format**

- When you declare a local variable inside of a method, the normal declaration syntax looks like:

```
Type varName = value;
```

- **The value part can be:**

- A constant
- Another variable
- A function (method) call
- A constructor invocation (a special type of function prefaced by **new** that builds an object)
- Some special syntax that builds an object without explicitly calling a constructor (e.g., strings)

30

## Declaring Variables in Methods: Examples

```
int x = 3;
int y = x;

// Special syntax for building a String object
String s1 = "Hello";

// Building an object the normal way
String s2 = new String("Goodbye");

String s3 = s2;
String s4 = s3.toUpperCase(); // Result: s4 is "GOODBYE"

// Assume you defined a findFastestShip method that
// returns a Ship
Ship ship1 = new Ship();
Ship ship2 = ship1;
Ship ship3 = findFastestShip();
```

31

# Constructors

Customized Java EE Training: <http://courses.coreservlets.com/>

Servlets, JSP, JSF 2.0, Struts, Ajax, GWT 2.0, Spring, Hibernate, SOAP & RESTful Web Services, Java 6.

Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

32

## Overview

- **Definition**
  - Code that gets executed when “new” is called
- **Syntax**
  - “Method” that exactly matches the class name and has no return type.
    - `public class MyClass {`
    - `public MyClass(...) { ... }`
    - `}`
- **Motivation**
  - Lets you build an instance of the class, and assign values to instance variables, all in one fell swoop
  - Lets you enforce that all instances have certain properties
  - Lets you run side effects when class is instantiated

33

# Example: No User-Defined Constructor

- **Person**

```
public class Person1 {  
    public String firstName, lastName;  
}
```

- **PersonTest**

```
public class Person1Test {  
    public static void main(String[] args) {  
        Person1 p = new Person1();  
        p.firstName = "Larry";  
        p.lastName = "Ellison";  
        // doSomethingWith(p);  
    }  
}
```

It took three lines of code to make a properly constructed person. It would be possible for a programmer to build a person and forget to assign a first or last name.

34

# Example: User-Defined Constructor

- **Person**

```
public class Person2 {  
    public String firstName, lastName;  
  
    public Person2(String initialFirstName,  
                    String initialLastName) {  
        firstName = initialFirstName;  
        lastName = initialLastName;  
    }  
}
```

- **PersonTest**

```
public class Person2Test {  
    public static void main(String[] args) {  
        Person2 p = new Person2("Larry", "Page");  
        // doSomethingWith(p);  
    }  
}
```

It took one line of code to make a properly constructed person. It would not be possible for a programmer to build a person and forget to assign a first or last name.

35

# Ship Example 3: Constructors

```
public class Ship3 {                                     (In Ship3.java)
    public double x, y, speed, direction;
    public String name;

    public Ship3(double x, double y,
                  double speed, double direction,
                  String name) {
        this.x = x; // "this" differentiates instance vars
        this.y = y; // from local vars.
        this.speed = speed;
        this.direction = direction;
        this.name = name;
    }

    private double degreesToRadians(double degrees) {
        return(degrees * Math.PI / 180.0);
    }
    ...
}
```

36

# Constructors (Continued)

```
    public void move() {
        double angle = degreesToRadians(direction);
        x = x + speed * Math.cos(angle);
        y = y + speed * Math.sin(angle);
    }
    public void printLocation() {
        System.out.println(name + " is at ("
                           + x + ", " + y + ").");
    }
}

public class Test3 {                                     (In Test3.java)
    public static void main(String[] args) {
        Ship3 s1 = new Ship3(0.0, 0.0, 1.0, 0.0, "Ship1");
        Ship3 s2 = new Ship3(0.0, 0.0, 2.0, 135.0, "Ship2");
        s1.move();
        s2.move();
        s1.printLocation();
        s2.printLocation();
    }
}
```

37

## Constructor Example: Results

- **Compiling and running in Eclipse**

- Save Test3.java
- R-click, Run As → Java Application

- **Compiling and running manually**

```
DOS> javac Test3.java
```

```
DOS> java Test3
```

- **Output**

```
Ship1 is at (1,0).
```

```
Ship2 is at (-1.41421,1.41421).
```

## Example 3: Major Points

- **Format of constructor definitions**
- **The “this” reference**
- **Destructors (not!)**

# Constructors

- **Constructors are special functions called when a class is created with `new`**
  - Constructors are especially useful for supplying values of fields
  - Constructors are declared through:

```
public ClassName(args) {  
    ...  
}
```
  - Notice that the **constructor name must exactly match the class name**
  - Constructors have **no return type** (not even `void`), unlike a regular method
  - Java automatically provides a zero-argument constructor if and only if the class doesn't define its own constructor
    - That's why you could say

```
Ship1 s1 = new Ship1();
```

in the first example, even though a constructor was never defined

40

# The `this` Variable

- The **`this`** object reference can be used inside any non-static method to refer to the current object
- The common uses of the `this` reference are:
  1. To pass a reference to the current object as a parameter to other methods

```
someMethod(this);
```
  2. To resolve name conflicts
    - Using `this` permits the use of instance variables in methods that have local variables with the same name
- Note that it is only necessary to say `this.fieldName` when you have a local variable and a class field with the same name; otherwise just use `fieldName` with no `this`

41

# Destructors

*This Page Intentionally Left Blank*

42

© 2010 Marty Hall

## Wrap-Up

**Customized Java EE Training:** <http://courses.coreservlets.com/>  
Servlets, JSP, JSF 2.0, Struts, Ajax, GWT 2.0, Spring, Hibernate, SOAP & RESTful Web Services, Java 6.  
Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

43

# Summary

- **Conventions**

- Class names start with upper case
- Method names and variable names start with lower case
- Indent nested blocks evenly

- **Example class**

```
public class Circle {  
    public double radius; // We'll make this private next lecture  
    public Circle(double radius) { this.radius = radius; }  
    public double getArea() { return(Math.PI*radius*radius); }  
}
```

- **Example usage**

```
Circle c1 = new Circle(10.0);  
double area = c1.getArea();
```

44
